MINING AND SCIENTIFIC PRESS.

AND PACIFIC ELECTRICAL REVIEW.

VOLUME LXX. Number 1. SAN FRANCISCO, SATURDAY, JANUARY 5, 1895. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

That Armor Plate.

Regarding the armor plate for the battle ship Oregon, referred to editorially in last week's issue, it may be further stated that the Government test was made on the 15th ult., at the Indian Head proving grounds. The plate was a seventeen-inch Harveyized nickel-steel plate, representing the forward thirteen-inch barbette of the Oregon. Members of the Naval Committee of the Senate and naval officers interested in ordnance matters witnessed the trial. The plate, which is one of thirteen forming a cylinder about the base of the Oregon's heavy turret, was not selected until the final treatment of all the plates it represented.

It is regarded by the Inspector of Ordnance, Commander Courtis, as the weakest one of the lot. It is twelve feet one inch long and eight feet four inches wide, and it weighs thirty tons. It was cast and forged previous to the test of the last heavy plate from Homestead, which was pronounced too soft, letting a Wheeler-Sterling projectile through it on the high velocity shot. The plate tested had been hardened more than the other and was regarded as being a typical Harvey plate. Owing to repeated assertions that the Wheeler-Sterling projectiles were better than other American projectiles, it was decided to test this plate with Wheeler-Sterling projectiles.

The first or cracking shot, an 850-pouud, twelve-inch shell, was aimed at a point five feet from the left end near the top, and on the edge of a soft strip intended for the purpose of securing the plate to the ship's deck. The charge was 278.30 pounds of powder; the velocity 1410 foot seconds, aud the energy 11,729 foot tons. The projectile penetrated fifteen inches and rebounded unbroken, shortened one-teuth of an inch and expanded in diameter eight one-hundredths of an inch. It spun violently on the ground, doubling up a heavy steel rail against which it happened to strike. The plate showed a crack extending from the right or ingot top end of the plate to the impact through the plate. This crack had apparently started at the edge of the plate aud run toward the impact, as it was fully half an inch wide at the former point and hardly open at the latter. The shot hole was also surrounded by a slight bulge in which were a number of radial cracks. This bulge, which was half an inch high and about thirty inches in diameter, indicated that the plate was somewhat softer than was desirable. It is to this reason that the penetration of fifteen inches can be ascribed.

The shot to determine the plate's resistanec to perforation was also a Wheeler-Sterling 850-pound twelve-inch projectile. The charge was 420 pounds of powder, the velocity 1858 foot seconds and the euergy 20,370 foot tons. This shot was aimed at a point about four feet from the top end of the ingot, thirty inches from the edge and twenty-four inches from the crack. The shell, after penetrating about ten inches, was shattered into minute fragments which rained down upon the proving ground for nearly a minute after it struck. The plate cracked from each impact to the upper edge, and the longitudinal crack was slightly widened. No bolts were broken or driven out, but the entire target was set back several inches, crushing some of the oak supports.

A rigid interpretation of the armor specifications would require the rejection of this plate and necessitate the successful trial of another plate before the $275,000 worth of armor could be accepted.

THE suspension of assessments was generally hailed as a satisfactory relief measure in '93; there was considerable difference of opinion as to its practical good in '94, and now comes up the questiou of the repetition of such congressional action for this year. The suspension helped thousands of individual owners and tided over many a man who would have been seriously inconvenienced to have had to do the necessary hundred dollars' worth of improvement on his claim. On the other hand, it kept from usual distribution some millions of assessment work, and in this way worked indirect injury to mining interests in general. The result has been very little assessment work done in the last eighteen months as compared with previous years, and it is questionable whether it would be wise legislatiou to re-enact the suspension bill in '95. Whether a gold claim or a silver one, it is more in the spirit of the times for owners, resident or non-resident, to have more development done. The required $100 simply complies with the letter of the law, and that much, and usually more, will be of benefit to each individual claim. There is great difference of opinion on this subject, as is always the case in matters affecting so wide an area, but the best interests of all and the proper development of the industry suggest that this year the law should not be suspended, and that the work of development be not checked. It is our belief that further effort in that direction would be unwise. As a matter of fact the suspension law has hurt the miner.

WIRE ROPEWAY OF THE ENGLISH MOUNTAIN MINE.

A Wire Ropeway.

The Vulcan Iron Works have erected one of their Wire Ropeways for the English Mountain miue, Nevada Co., Cal., to be used for transporting gold ore from the mine, situated on the side of a steep mountain, to a twenty-stamp mill below on the flat, a distance of 2800 feet, air liue, with an elevation of 600 feet. The nominal capacity of this line is 100 tons in ten hours.

This line, a partial illustration of which herewith appears, is not as remarkable as some other lines erected by the Vulcan Iron Works for leugth, high fall, long spans, etc., but is especially important in the fact that, were it not for this mode of transportation, it would be practically impossible to work this mining property, as the miue is situated on the side of a precipitous and rocky mountain and the expense of preparing any surface line dowu the mountain and across the lake would be enormous. In the region where this miue is located there is a snowfall of fifteeu to twenty feet, but such deep snow in no way interferes with the successful operation of this ropeway, permitting the active operatious of carrying the ore, to go on through the severest winter weather.

This line is provided with automatic loading and dumping machines, and being a gravity line, *i. e.*, the loaded buckets carrying the unloaded back, the cost per ton transported, is extremely low.

MANY causes are assigned for the financial stringency. On this coast the shrinkage in production may be pointed to as the principal one. Take California: The wheat crop of '80 was worth $40,000,000: the wheat crop of '94 is worth $13,000,000—a loss of $27,000,000 on that one product. The shrinkage in the value and quantity of Nevada's silver yield is another case in point. As compared with '80, it is within bounds to say that there is a diminished product of $50,000,000 in the two States. That is just so much less to spend, and that, too, among au increased population in this State. Were it not for the gold output of the State, matters would be much worse. The gold yield of '93 shows a haudsome increase over the previous year, aggregating $14,422,811, aud it is believed the total for '94 will exhibit the same gratifying result.

OBJECTION is often made to taking stock in proposed incorporations, that the holders of a majority of the shares have the power to levy assessments aud cause the sale of delinquent shares. It has been urged that a chauge is requisite in the State laws in line with similar enactments in some of the Eastern States, to the effect that where shares iu a stock company become delinquent by uon-payment of assessments, they stand as a debit against the stock so held, with interest, if so ordaiued, till paid; but that the delinquent stock could not be summarily sold. Such a law would interfere with auy "freeze-out" proposition, and would dispel an uncertainty that often exists under present rulings.

TABLE OF CONTENTS.

ILLUSTRATION.—Wire Ropeway of the English Mountain Mine, 1.
EDITORIALS.—That Armor Plate; A Wire Ropeway; Miscellaneous, 1. The Money Question; Miscellaneous, 2. Money Asked For, 3.
CORRESPONDENCE.—The Cyanide Patents; Eastern Oregon Prospects, 4. Mining in Nevada County, Retrospective and Prospective, 5. Tuolumne Mines, 6.
SCIENTIFIC PROGRESS.—A Chemical Curiosity; Four Hundred Degrees Below Zero; The New Constituent of the Air, 8.
ELECTRICAL PROGRESS.—Direct Conversion of Light Into Electricity; France Encourages Electrical Progress, 12.
PRACTICAL INFORMATION.—Wages of Steamship Building; The Speed of Trolley Cars; Doesn't Pay to Pick Up Nails, 13.
MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 10.
THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 14.
MISCELLANEOUS.—Concentrates, Personal; Obituary, 3. Laboring at High Altitudes, 4. Right Kind of "Salt," 6. Quicksilver, 7. A Big Copper Deal Predicted, 8. An Explosion in an Iron Foundry; Machinery of a Cruiser; Armor Plate for Russia, 12. Coast Industrial Notes, 10. Recent Patents, 14.

THE Victoria *Colonist* makes a stroug appeal for the establishment of a mining bureau in that provinee. British Columbia needs such an institution. Without a mining bureau, no State or provinee can expect to have its mineral resources properly developed.

THE *Chronicle*, iu its New Year's edition, gives a very good summary of the eondition aud progress of the State in '94. Its prophecies regarding 1945 make very pleasant reading, although it is always easy to create an atmosphere in which to flap the wings of fancy. The possibilities exist, the opportunity is ours, and the result will be commensurate with the effort made. "California and Its Possibilities" is a grand theme, and the *Chronicle* has done it justice.

A LARGE NUMBER of papers published in the interior of the State are advertising the best or quickest way to reach the South African gold fields. In this regard it should be generally understood that uo one should leave this State in hopes of improviug his financial condition in South Africa unless he has guaranteed to him by responsible parties, before starting, a good position at fair wages. Otherwise, he will be grievously disappointed.

THE extraordinary raiufall on the coast and in the valleys meaus the piling up of immense snow in the mountains. "The first snow that falls is the last snow that goes," aud the present wetness meaus abundanee of water for the miner uext season. The snow causes considerable present inconvenience. At La Porte, Plumas Co., last week it was ten feet deep on the level, and no mail had reached there for eight days. Near the Mountain House, on the road from Nevada City to Downieville, the snow was twelve feet deep ou the stage road.

THE recent sale of the Oregon Pacifie railroad for $100,000 illustrates the uncertainty of railway investments and the folly of puttiug good money into a scheme not thoroughly uuderstood. Begun in 1880, when Heury Villard was acquiring possession of the Columbia river, the Oregon Paeific people started a railway from an alleged port at Yaquina, Or., toward the Willamette valley, with the announeed program of completion 600 miles to Boise, Idaho. The enterprise was backed by New Jersey capitalists, who said the ultimate intention was to have Eastern transeontinental connection made. A line of steamers was put on to this eity, and the projeet was widely boomed. First and last the work cost about $11,000,000. There are outstanding $15,000,000 of bonds, several additional millions of stock, and about one million in unsecured debts. The stock is valueless, and should the bondholders hope to get anything back on their investment they must advanee a great deal of money. All there is to show for the vanished millions is 147 miles of railway. The trouble was lack of water at Yaquina.

THE Boston *Transcript* thinks "Moribund Nevada's two Senators for 40,000 people are the shame of the uation." The natiou has shames, but Nevada's Senators are not of them. If it be redistribution that our Boston brother believes in, what shall his basis be? Rhode Island, like Nevada or auy other sovereign commonwealth, has two Senators. If on a basis of population, then the East will suffer thereby. New England has fourteen Seuators now. Illinois has two; but, if the New Englaud basis is the correct one, Illinois should have ten, and other States are in like proportion.

W. S. STRATTON of Cripple Creek, Colorado, is the latest mentioned iu connection with the United States Senatorship from the Centennial State. In the last two years he has risen from financial obscurity to promineuce. Jas. Haggin had an opportunity to have some of the Colorado man's present wealth, but was a little slow. One big mining property was offered Haggin by Stratton about fifteeu months ago for $155,000. The financial flurry made him temporize, but he sent a trusted friend to make inspection of the property, who wired him the mine was easily worth half a million. Haggin telegraphed Stratton the same hour that he would give $350,000 cash for the property, but the answer flashed back was: "One million wouldu't buy it."

THE continued decline in the price of silver during '93 and '94 has caused mueh comment on the futurc of silver mining. The *Tribune* says that, in Utah, consolidation is proposed. With the decline in the price of the metal the profits are shrinking so fearfully as to endanger the existenee even of the largest and richest properties. Already hundreds of the small mines, which were making money two years ago, have surrendered and given up the business. Sueh fate will overcome the larger mines unless steps of some sweeping sort, amouuting almost to a revolution in methods, can be devised. Those steps, say some of the leading miners, must be in the direction of the eonsolidation of iuterests. Silver mines in given loealities must unite in the same manner that so many other industrial enterprises are uniting. That will make sueh a reduetion of expenses possible as will partially offset the terrible decline in priee which has been taking place since the panic. It will also fortify the producers as against the smelters aud refiners, and in that way, if it were to be iu no other, effect a considerable ehange from present couditions.

AMONG other matters decided at the recent State election there were several constitutional amendments voted upon affirmatively, one relating to the foreign ownership of real estate in California. Section 17, Artiele I of the State Constitution has been by popular vote ameuded so as to read as follows:

> Section 17. Foreigners of the white race, or of African descent, eligible to become citizens of the United States under the naturalization laws thereof, while bona fide residents of this State, shall have the same rights in respect to the acquisition, possession, enjoyment, transmission and inheritance of all property, other than real estate, as native-born citizens; provided, that such aliens owning real estate at the time of the adoption of this amendment may remain such owners; provided, further, that the Legislature may by statute provide for the disposition of real estate which shall hereafter be acquired by such aliens by descent or devise.

From London comes the inquiry: "How will this affect English ownership of California gold mines? Are not gold mines 'real estate'?" Accompanied is an implication that the recent voice of the people so vociferously expressed may result in cessation of purchase of California gold mines by the British iuvestor. On the assumption that the next best thing to having our mines owned and operated at home is to have foreign capital so engaged, it were unwise to put auy obstacles in the way of "foreigners" investing and profiting by such investments here. Gold mines eome under the heading of real estate, but it is not at all likely that the Legislature whieh meets next week at Sacramento will take any further action inimieal to the foreign investor in gold mines or other real estate in Californiа.

The Money Question.

The currency question, the issue of bonds, "free eoinage," etc., take up the public thought in and out of Congress. Many plans are offered, the one now before the House, known as the "Carlisle plan," and which deserves defeat, being the one receiving the most present attention.

In the discussiou of a question two things must be observed: What is the question, and on what points do well-iuformed persons agree?

On the money question all intelligent men agree that a contiuued increase of circulating medium causes the general level of prices to rise and a contraction of currency causes a shrinkage in prices.

What is the free coinage of gold and silver? It has been so often misstated that it is well to state it fully. The Governmeut of the United States alone has power to say what shall constitute a legal tender in the payment of debts, aud to determine the relative coinage value of gold and silver. What is meant by free coinage is simply this:

The Government will eoin all the gold bullion brought to the mint so many grains to the dollar, charging therefor, if it sees fit, a mintage charge, and the owner of the bullion takes the gold dollars his bullion makes, and takes his own chances of circulating them. Such is the law to-day. If we had free coinage of silver, the same thing would obtaiu as to silver bullion. The owuer of silver bulliou would take his bullion to the mint and have it coined into silver dollars (the Governmeut making a mint charge), the owner of the bullion receiving silver dollars and taking his own chances of placing them in circulation. In neither case does the Government buy the bullion.

What then beeomes of the favorite assertion so ofteu made that, if we have free eoinage of silver, the owner of silver bullion will bring his silver here and sell it to the Government for gold? It is not the case, for the Governmeut does not buy it, nor have anything to do with it except to coin it, deducting a mintage charge and making by law the dollars a legal tender. The owner of the bullion has on hand the same bullion he puts in the mint, changed in form and less in amount equal to the mint eharge.

It is again stated that to do this is to repudiate our government contracts. This is not so.

All the bonds of the United States, even those recently issued, are payable in *coin* (they do not say gold coin) of the weight and standard of fineness of July 14, 1870. We find, then, under the law of 1870, gold and silver were full legal tender at the ratio of 16 to 1, the silver dollar being 412½ grains, nine-tenths fine, and the gold dollar being 25.8 grains, nine-tenths finc.

In what mauner would it be repudiation to pay our bonds just as we agree to?

As to the effeet: If we have gold alone, or a limited amouut of silver, the effect is to cause a steadily decreasing amount of money, for the output of gold does not keep pace with the amount used in the arts and worn out and lost, and with the eonstant inereasc of population the effect on prices is to eause a constant decline, the men with fixed incomes from bonds and life salaries being correspondingly benefited, and the burden of paying the public debt being correspondingly harder.

If we had free coinage of silver as well as gold, the circulating medium would either increase, or at least the tendeney to further deeline would be checked. Objections are urged to the coinage of silver, but they are all based upon prophecies, and they are the same that were once made to the coinage of gold in Europe in 1857, when gold was demonetized by the most of the leading nations of Europe. They are the same prophceies that were made in 1878 in Congress, when the Bland bill, providing for the coinage of $2,000,000 a month, was on its passage.

Not one of the evils so eloquently prophesied in 1878 occurred. Then men should cease their prognostieations of evil or, at least, sometimes make a prediction that eomes true. Can we do this thing alone? In the struggle for gold alone we are strong enough to enter the race. If we ean do that we eertainly ean be an independent nation. If our exports exceed our imports money must come to us. If our imports exceed our exports we must in time become bankrupt under any system.

Money Asked For.

The committee for the protection of mineral lands is having printed 5000 pamphlets to be sent to the miners of the State, setting forth the facts in the present effort to stay pending action and secure such legislation as will enable the miner to stand on more equitable terms as to the selection and disposition of public land. Much of the contents has already appeared with endorsement in these columns. The motive of the present distribution is to show the present status of the matter, illustrate the necessity for prompt action and direct attention to the fact that money is needed to bring the movement to a successful issue.

The pamphlets, which will be issued next week, contain the following appeal:

To the Miners of California: Until the organization of the California Miners' Association, a few years ago, united action on the part of the miners of California was practically impossible. Now, however, with branch miners' associations in the mining counties (all of which are represented on the executive committee of the main association), the miners are in a position to make their wants known as a body and bring their grievances before the Legislature or Congress with some assurance of attention being paid to their requests. At the annual miners' convention the delegates are enabled to instruct the executive committee as to the course to be pursued during the year, and to various sub-committees are intrusted the responsibility of carrying out the resolutions of the convention.

Owing to the exertions of the California Miners' Association a radical change has been made in the Federal laws relating to hydraulic mining in this State, under which these mines, long closed down in certain sections, may again, under prescribed conditions, resume work and become profitable, giving employment to many men. The Miners' Association now has on its hands a struggle to effect certain changes beneficial to the miner, on the laws relating to quartz and drift claims. It is also endeavoring to prevent further encroachments on the public mineral domain by agricultural or railroad claimants, so as to keep for the miner the heritage which is his due.

To carry on this work properly and accomplish the results desired by the convention money is absolutely necessary. With the single exception of the secretary, who has abundant work to perform, no man in the association receives any salary or money, the work being all done voluntarily by the executive and other committees. It is, however, necessary to employ people to prepare maps, look up records and perform other services for the committees. A great deal of printing is also necessary, and money is needed for that. It may also be necessary to send some one to Washington on behalf of the Miners' Association to look after our interests there. We ought to have a fund on hand for such emergencies as are apt to occur. Without money it is impossible to carry out the wishes of the association.

All this work is being done in the interest of the mines and miners of California, so in helping the association with funds the miners are helping only themselves. With the changes in the laws we are advocating will come better times throughout the mining regions of the State, more investments of money and the consequent employment of more men. The miners must themselves put their hands in their pockets if they wish to see anything accomplished. The hands of the executive committee are tied when they have no funds to carry on their work.

Those opposed to the interests of the miners are abundantly provided with money, lawyers, and facilities of all kind to accomplish their ends, and if we are not measurably equipped in the same way we will have an up-hill fight and be liable to accomplish little. Not a cent of the money collected for the purposes of the association is wasted or extravagantly used. Those who contribute may rest assured that the funds are carefully guarded, and account given of all expenditures. The amount on hand now is less than $100 and there is need for at least $1000 at once for certain expenses incurred. Other similar expenses are bound to follow and we should have several thousand dollars in the treasury.

According to the report of the State Mining Bureau this year there are upward of 13,000 miners employed in the mines of this State. A contribution of $1 each would provide an abundant fund to carry on the Miners' Association for some time. If superintendents and managers of mining properties would make a very slight effort to explain the objects and purposes of the association and its needs, the men would willingly contribute their share. Merchants and storekeepers in the mining towns should also be called upon to assist the movement. The county associations, through their officers, should appeal to the members to aid the good work.

Appended to this are certain documents showing, among other things, what other mining States are doing in the direction of saving the mineral lands for the miner. It is in direct line with the work California has before her, and upon which the association has a committee now engaged. It would repay every miner in the State to read these statements, as they show the danger we incur of being apathetic or postponing action on matters relating to the mineral lands. All these matters must at once be brought to the attention of the Government authorities in as forcible a manner as possible. Delay at this time means a forfeiture of thousands and thousands of acres of mineral land. The miners can keep this land for themselves if they make a united effort, but if they fail to do so it will be their own fault. The State Association is in a position to represent the miners' interests provided it is furnished with the necessary funds to carry on its work.

Obituary.

JAS. G. FAIR, ex-Senator from the State of Nevada, and a miner known the world over, died at the Lick House in this city on the night of the 28th ult., in the 64th year of his age. Born in Ireland in 1831, he came here at the age of 19, and mined with varying success, till he, with Mackay, Flood and O'Brien, secured control of the Virginia City mines, that yielded them $150,000,000. The stories told of "Uncle Jimmy Fair" are countless. He was a hard worker, a shrewd manager, a good practical miner, the best, in fact the only real miner in the big quartet whose riches made them famous. While luck had a great deal to do with his results, he was that style of man that left little to chance, but so acted that everything would come his way unless all known laws of circumstance failed. He was a power in the mining world, the biggest of big operators in the Stock Exchange, and his nerve and financial ability were such that he could withhold and overcome the greatest of financial flurries. As a money maker he was a gigantic success: his estate will probably aggregate $30,000,000. Twenty-five years ago he was a poor man; ten years ago he was reckoned at $15,000,000. His real estate and mining investments all turned out well, and the only place he made other than a great success was in the U. S. Senate, where, like Stanford, he never felt at home, not being able to say or do what he liked.

In every department of industry he had big investments, and he gave constant employment to an army of men. He did a great deal for this city, spent millions of dollars in industrial enterprises here, improved his real estate, and kept money constantly moving.

His millions go to his three children, Mrs. Oelrichs, Miss Fair and Chas. L. Fair, but are so curiously tied up in his will that they practically have only a life interest in his wealth.

Concentrates.

THE Montana Ore Purchasing Company has declared a dividend of $40,000.

THE "Minnesota Gold Mining and Refining Co." have been proved to be frauds.

THE Starlight mine, El Dorado, has been sold to G. C. Hawley of this city for $25,000.

THE White Swan mine, near Baker City, Or., has been sold to Des Moines, Iowa, capitalists.

THE Boston & Colorado Smelting Company paid a 2½ per cent quarterly dividend on the 2d.

A "STRIKE" is reported in the 1600 level of the Maryland mine. The lodge is about twenty-five inches in width and shows free gold.

THE Redding *Free Press* says: "The Gladstone mine at French Gulch has settled every dollar of indebtedness, and is ready to turn out bullion."

THE Sioux mine, at Tintic, Utah, has been sold to F. Farrell, of Ansonia, Conn. A big reduction plant will be at once built, including a 100-ton concentration mill.

C. G. W. LOCK and Thomas Hall of Deadwood, S. D., have sold to the California Picacho Gold Mines Company the Ruhy placer claim in the Picacho district in San Diego county.

THE Congress mine, Arizona, has been sold to the syndicate headed by E. C. Gage, who is at present in charge of the property. It is understood that the price paid was $1,000,000.

NEW MEXICO'S mineral output in 1894 has not yet been officially figured up, but the most reliable data show: Gold, $1,500,000; silver, 1,250,000 ounces; lead, $80,000; copper, $50,000.

THE Indian Creek L. & M. Co. are working the Shaw mine, near El Dorado, and will shortly build a 50-stamp mill. Nearly a quarter of a million was produced by the Shaw mine in days gone by.

THE Secretary of the Interior has approved the lists of land selected as indemnity by the Northern Pacific railroad, embracing about 200,000 acres in the Minnesota grant and 300,000 in Montana.

THE Horse Shoe Gold Mining Company, of Wardner, Idaho, has incorporated; capital stock, $1,000,000; officers: F. Jenkins, president; G. W. Harris, vice-president; H. Drought, treasurer; H. A. Jones, secretary.

IN the mineral production of Idaho for 1894 the totals are: Gold, $,879,000; silver, $2,359,000; lead, $3,606,000; an aggregate of $7,884,000. Silver is figured at sixty cents an ounce and lead at three cents per pound.

THE Consolidated South Spring Hill Gold Mining Company has incorporated, and John R. Tregloan is superintendent. They will work the Median mine at Amador City. The incorporators are residents of Portland, Maine.

THE directors of the Harqua Hala mines have transferred to Wickenburg the shipping of supplies to their property. The road is by way of Cullen's wells, the only drawback being the lack of water on a stretch of forty miles after leaving Wickenburg.

THE electrolytic plant of the Boston & Montana Company at Great Falls, Mont., which was originally expected to produce 800,000 pounds of copper per month, is reported producing more than twice as much and at a very slight increase in cost.

CHICAGO PAPERS quote C. M. Kepp of Milwaukee, a shareholder in the Gem mine, as saying that an English syndicate is likely to purchase the Gem, Frisco, Tiger and Poorman mines of the Cœur d'Alenes. The consideration named is $3,000,000.

THE Osceola Copper Mining Company will pay a dividend of $1 per share on the 15th, the first since December 30, 1893, when a similar amount was paid, and also $1 on May 5, 1893. The dividend payable on the 15th will make a total of $1,897,500 to that date.

A. GROTHE, of Payette, Idaho, who recently returned from London, succeeds J. C. Kemp Van Ee as manager of the Poorman Mining Co.'s mines at Silver City, Idaho. A new mill will be built in the spring, and it is understood that a development fund of $150,000 is available.

THOUGH silver is but sixty cents an ounce, Tombstone, Arizona, is said to be turning out 150 tons of ore weekly that brings back from the smelter between $9000 and $10,000. In addition to this, her miners are piling up reserves of ore for the time when silver shall be rehabilitated.

THE Columbia River hydraulic mine is now owned by the American Development Company of Duluth, Minn. The property consists of the Discovery claim of 65 acres and 160 acres adjoining, together with a water right, in the big bend of the Columbia about 75 miles north of Revelstoke, B. C.

TEXADA ISLAND gold is the subject of discussion in Nanaimo. Several excellent specimens have been exhibited showing a considerable quantity of free gold; but to experienced eyes it looks a trifle too much like the product of a "specimen mine" with a vein so small as to require almost solid metal to work.

SHELBY ELI DILLARD asserts that "the great trouble with the majority of prospectors is that they are afraid to use the pick and shovel. It takes plenty of hard work and good judgment to prospect for mineral. This thing of going to the mountains and laying in camp and eating three meals a day and telling old-time stories about what was found in California forty-nine years ago, is only mythical gold hunting. It takes a brave heart and bull-dog determination to get rich in the mining business, and people who are not endowed with such characteristics had better leave mining alone."

THE Rosemont, Arizona, copper mines have closed down. Very little development work has been done on the property, and it was found to be a piece of folly to try to maintain an eighty-ton smelter running on surface ore. This is but another instance of the uselessness of erecting reduction works before having a mine.

THE Interior Department decides that 128 acres of land, upon which most of the residence houses of Cripple Creek are located, has been declared placer ground and the ownership awarded to half a dozen claimants. There are about 500 houses on the claim, and the owners will have to pay for the land they occupy or move off.

THE Little Larb Hills, near the Choteau county line, in Valley county, Montana, is the scene of the latest gold find. It is thought there that the new gold fields will prove as great a source of wealth as did the deposits at Alexander City, near Glasgow, last spring, when all Montana was threatened with a stampede.

As elsewhere, the closing of the silver mines, caused by the low price of silver, has resulted in a marked increase in the gold production of Arizona. The gold output during the year was $2,080,250; the silver output $1,700,800; copper, 48,270,500 pounds. The total output of these three metals for the last eighteen years is valued at $101,784,017.

A BUTTE, Montana, mining broker is told in a letter from Liverpool, England: "The mention of a gold mine or any other kind of mine to a Liverpool man is fraught with danger. Liverpool has suffered fearfully by mining ventures, especially during the Australian craze of 1888, 1889 and 1890, when shares sold from £2 or £3 which now cannot command as many shillings."

MAJOR NEWELL, who is the inventor of a scheme to raise gold-bearing gravel from the bed of a stream by means of a strong suction pipe and extract the precious metal therefrom, has launched his craft on Rogue river, near Grant's Pass, Or. The boat is thirty feet long by twelve wide, and is fitted with an engine and boiler to run the pump and a set of sluice-boxes to wash the sand and gravel after it has been raised to the surface.

THE Southern Pacific Railroad Company has filed in the Visalia Land Office a list of land situated in the Visalia district and has applied for a patent for the said lands. The total for the district amounts to 65,529.90 acres, which are in townships 25 S, and 29, 30 and 32 E; 26 S, 29, 30 and 32 E; 27 S, 32 E; 29 S, 21, 22 and 23 E; 30 S, 21, 22 and 23 E; 31 S, 22 and 23 E. Those interested in these lands must put in their protests, and file them in the Land Office at Visalia before the 28th inst.

Two years ago a contest was begun in the Spokane, Wash., local land office against issuance of patent to the Oro Fino placer mine, owned by S. I. Silverman. The local officers rendered a decision against him. He appealed to the Commissioner, who reversed the findings of the local officers. The case was carried to the Secretary of the Interior, who reverses the Commissioner and sustains the original decision. The case is especially important to the town of Loomiston, which is laid out on the placer claim.

THE Nevada Southern railway, a branch of the Atlantic and Pacific, is now completed to within a few miles of the southern boundary of Nye county, Nev., and the contractors expect to enter that county early next spring. There are large deposits of gold and silver-bearing ore in Nye and Lincoln counties, carrying from $30 to $60 per ton in gold and silver. This ore cannot be worked profitably until cheaper transportation facilities are obtainable. The completion of the Nevada Southern railway will result in the development of the mines of Nye and Lincoln, and there will be a large immigration to those counties next year.

THE following articles of incorporation have been filed with the County Clerk of Amador county: Articles of incorporation of Consolidated South Spring Hill Gold Mining Co.; capital stock, $1,500,000; amount of stock paid for, $35; par value of the shares is $5; located at Portland, Me. Lone Hill Mining Co.; capital stock, $150,000, divided into 75,000 shares—par value $2 each; place of business, Sacramento, Cal.; to exist fifty years. Reward Gold Mining Co.; capital stock, $1,000,000, par value $10 per share; capital stock subscribed, $25,100; place of business, San Francisco; to exist fifty years. Amador Railroad Co.; capital stock, $100,000, par value $100 per share; capital stock subscribed, $12,400; place of business, Amador City, Cal.; to exist fifty years.

THE Leadville, Colorado, *Herald-Democrat* gives the total output of that camp for 1894 at $8,160,074. If silver had been at its coinage value the output would have amounted to $13,000,000. Of the 1894 output, the production of gold amounted to $1,934,240. This, says the *Herald-Democrat*, is certainly an excellent record for a gold camp but a year old and with but three gold properties practically producing at this time. The gold output for 1893 was only a little over $803,000. The tonnage of the camp for 1894 as given is 362,907 tons, which is an increase over 1893, when there was but 340,000 tons of ore brought to the surface. The great Smith-Moffat group, including the Maid of Erin and Gray Eagle, consolidated, has taken out 10,000 tons more than last year, and many of the other older properties show a like increase. The grand total of the yield of Leadville mines from 1879 to 1894, inclusive, is $196,449,447.29. The number of men engaged in mining, hauling and smelting ore, as furnished by the superintendents of the different mines, is divided as follows: Miners and mine laborers, 2231; smelter hands, 650; ore haulers, 150.

Personal.

M. BOOTH succeeds Mr. Bache as assayer for the Treadwell company.

JOHN GILL succeeds M. G. White as foreman of the Granite Hill mine, Nevada Co.

W. M. NESBIT SR. will take charge as superintendent of the Mammoth mine at Tintic, Utah.

MRS. PHŒBE A. HEARST of this city has provided for the miners of Lead City, S. D., a library and reading-room in the new building of the miners' union.

F. B. PLEBY, a mining expert for Senator J. P. Jones, has gone to Mexico at Metlakatla to look over the late gold discoveries in quartz on the north side of Annette island.

The Cyanide Patents.

To the Editor:—Serious misapprehension appears to exist in some quarters respecting tbe effect and scope of tbe recent decisions of the English courts against the plaintiff in the suit brought for infringement of one of the MacArthur-Forrest patents.

Preliminarily, it should be observed that tbis decisiou was by a single trial judge, and at what may be regarded only as the commencement of the litigation. Such initial decisions are far from conclusive, and are subject to revision and reversal by the Court of Appeals composed of several judges, and after tbis again by the House of Lords, where many a patent has been sustained after being invalidated below. In fact, it may be stated almost as a rule that in cases involving difficult chemical processes, like the MacArthur-Forrest patents, the invention rarely comes to be fully understood and its merits recognized and rewarded until after the full and repeated discussiou and study arrived at in the higher and appellate courts as compared with the hurried first conclusions of the trial below. A striking instauce of this is afforded by the history of the Tilgman patent in this country for reducing fatty acids by a chemical process. That patent—in many respects closely analogous to the MacArthur-Forrest patent—was first held to be void, not only by the courts below, but even by the Supreme Court of the United States (See report of Mitchell vs. Tilgman, 19 Wallace U. S. Reports, 287). One would suppose that the Tilgman patent was finally disposed of after an adverse decision by the highest appellate tribunal in this country, and that those wishing to use the process might thereafter do so with impunity. But tbe exact contrary proved to be tbe case, for in a few years afterward, in another suit, the Tilgman process again came up on appeal before the same Supreme Court; but on this second occasiou the court, having become better instructed as to the nature of the invention and its great utility, actually reversed its own prior decisiou and sustained the patent in the broadest possible way (See report of Tilgman vs. Proctor, 102 U. S. Reports, 707).

However, there are many other reasons besides the possibilities of the appeal why the English decision should not in any sense be depended upon as weakening in any way the right of the owners of the MacArthur-Forrest patents in this country to insist upon the recognition of their rights. The only question presented in the English court arose on the broad claim to the exclusive use of a cyanide of potassium solution for extracting gold from ore. The second or more specific claim to the use of the solution, after the manner and in the proportions which seem most useful as invented and disclosed by Messrs. MacArthur and Forrest, was not involved in that case. The whole sum of the decision was merely that, so far as this first trial judge could see, Messrs. MacArthur and Forrest were not entitled to the exclusive use of every possible form of cyanogen and of cyanide solution. The claim of the American patent is, as is well known, narrower and more specific than this broad English claim, and is carefully limited so as to cover only a specific strength of cyanogen, which latter, it may be added, is the only kind of solution which has been found effective in this country. There is, therefore, no ground for supposing that the English decision constitutes any precedent which will control or even affect in any way the result of the suits against infringers on the American patent, which are now under way.

Furthermore, it should be borne in mind that the MacArthur-Forrest process is not, as patented, merely for the use of cyanide of potassium. The use of cyanide constitutes only one feature of the invention, and this was the only part of it involved in the English case. As will be well understood by those familiar with the process, other additional features of great importance are covered by the patents, among which may be noted the present admirable method of precipitating by the use of zinc shavings. Though other methods of precipitation are open to the public, this particular one is covered by a patent, the validity of which is believed to be unchallenged. It should be said, in conclusion, that no patent of any distinguished value has ever run its career without the most violent opposition and question as to its validity, and that it cannot be anticipated that these patents shall enjoy any exemption from this general rule.

Considering the enormous value and utility of the process as demonstrated by the actual figures of those working with it, and on the undisputed fact that no one ever actually brought it into use until Messrs. MacArthur and Forrest published it, it would seem but just to accord to them, as a slight reward for their patenting and thus teaching to the world that which otherwise they might have kept as a secret process, the few years of monopoly during which they may get some return through the moderate license fees, on payment of which the process is freely opened, with fullest instructions, to all the mining world.

It does seem incredible that these inventors should have been anticipated by others when it is considered that no problem has received keener or more constant scientific and practical attention during the last fifty years than this—of how to extract from ores the percentages of gold resisting amalgamation, chlorination and other processes, and that the scientific publications of Faraday, Gemlin and others, and the patent of Rae, relied upon as anticipations, were all on the books for more than thirty years, notwithstanding which no one knew enough to make any use of such publications until *after* Messrs. MacArthur and Forrest had demonstrated the enormous utility of this process. The fact is, that none of these publications disclosed what MacArthur and Forrest subsequently taught, and that were it not for the latter the mining world would today be just where it kept for thirty years, notwithstanding all those publications stared it in the face during the entire time. H. Bankart, M. E.

San Francisco, Dec. 26, 1894.

Eastern Oregon Prospects.

To the Editor:—The mining fields of the Northwest have been unusually active for the past three years, and during that time many valuable discoveries have been made and transfers of mining property numerous. True, the debasement of silver had a very disastrous effect upon certain productive districts, but even this state of affairs did not deter the prospector from searching for silver lodes. The feeling that sooner or later the white metal would receive recognition that would place it on equality with gold encouraged him in his explorations. The general character of the ore in this section of the western mineral fields, even in the face of the great decline in silver, stimulated the searcher for wealth owing to the fact that the silver-bearing districts carry a paying percentage of gold. Many of the best paying mines throughout the Northwest, though predominating in silver, depend mainly upon the diffusion of gold throughout the ore for profits, and but for which such properties could not be successfully operated. The mines at De Lamar are a striking illustration of this fact, the gold product being in excess of running expenses.

In this section of Grant county this characteristic of ores prevails, and though the old parity of the two moneyed metals should never be restored there is sufficient wealth in the ores where large bodies of it exist to insure productive and valuable mines. If this mineral belt existed in any of the more favored States and Territories it would long ago have been an important factor in the world's product of both gold and silver, but for reasons of a financial nature ledges of the most promising description were not sufficiently prospected to prove the extent and value of ore bodies and of course could not be represented to mine buyers as they deserved to be. In nearly every instance where thorough development has been a feature paying ore bodies have been unfolded, and that, too, in mines where croppings showed but little mineral. The La Belleoue, one of the most prominent mines in the district and now operated by a strong syndicate, is corroborative of this fact.

The Greenhorn mountains are undeniably rich in minerals, and it is only a question of time when development will demonstrate the existence of ore bodies of incalculable importance to the mining world. The belt is extensive, the ledges large and running parallel, and so close together that in some instances five or six ore-bearing veins exist within the side limits of a location and an opening on any one of them would suffice for operations on the entire group. The ores are, however, refractory and would therefore necessitate roasting; but in a country so densely timbered, the output of the mines can be treated in this manner at comparatively light cost. As a general thing, ledges in high altitudes very rarely carry much gold, but here it is an exception. The ore is very similar to that in the DeLamar mines in Idaho and would require the same treatment, but owing to far superior natural advantages, the cost of reduction would be nominal compared with the expense attending the ores in the mines above mentioned. Again, nearly all the discoveries made can be opened at great depth through the medium of tunnels, cross-cutting the country or projected along the veins, thereby opening up long-lasting ore bodies and precluding the employment of pumps and other machinery necessary where properties are operated through a shaft. No opening of sufficient depth has as yet been made to fully demonstrate the nature of the country, so far as water is concerned; but even though the formation should hold quantities of it, a long time must elapse before the stoping territory above a tunnel level would be sufficiently exhausted to necessitate sinking.

Nature could not have done more in the shape of natural advantages for the successful working of the properties, even though Providence has taken especial efforts to do so. As before stated, the mountains are densely covered with the best of timber for building and mining purposes. Water is plentiful, and fall can be obtained for running any machinery of whatsoever nature for working the mines or treating the ores. The snowfall, though probably reaching the depth of seven or eight feet, will be no obstacle in mining, the roads being easily kept open. A fine mountain highway leading from either Baker City or Canyon City via Granite, penetrates the Greenborn country, and from which branch roads run to the different mines. By the way, there is a narrow gauge railroad running from Baker City to the village of McEwen, a distance of twenty miles, and your correspondent has been informed that this road will be extended to Fort Sumter next season, thus bringing Granite within fourteen miles of railroad communication and the Greenhorn mining district within thirty-two miles of the railway terminus.

The entire country is picturesque; the mountain scenery is embellished here and there by beautiful lakes filled with the finest trout, while in every direction little streams wind their way, all of which are well stocked with speckled beauties. Game of every description natural to this latitude is plentiful. The climate is delightful, and, viewed impartially, it is undoubtedly one of the most interesting mining camps on the continent.

Though but a few years have been devoted to prospecting in this district, a number of fine locations have been made and nearly all of them have received more or less development. The "Intriusic," operated by a Portland, Oregon, company, is a fine property, located on the east side of the mountain and distant from the old town of Robinsonville about two and one-half miles. The ledge is a large one, the ore being gray copper carrying gold. Five tons of ore were shipped from this mine that returned an average of 112 ounces in silver and $5 per ton in gold. The Silver Hill, owned by Schuarr & Hann, also has a record as a high-grade mine, in the neighborhood of fifty tons of ore having been treated that yielded 268 ounces in silver and $5 per ton in gold. Messrs. Miller & Morris are developing a mine known as "Morris," that promises to become very valuable. The mine is opened through a tunnel and several hundred tons of ore have been extracted and shipped that yielded $48 per ton in gold and silver. The "Ornament" comes next in rotation and is also operated by a Portland combination, the ore being of the same character as that in the mines above mentioned. The Bennet claims, in the same vicinity, have been developed to some extent and all the ore tested has yielded well. The Ruby and Chloride mines, located near the head of Boulder creek, are other properties of great promise, and during next season will be operated for all they are worth.

On the north side of the mountain a stream, known as Lost creek, finds its source, and on the headwaters of this creek is located one of the best mineral belts in Oregon. Within a comparatively small area of territory twenty veins have been prospected, all of which show remarkably well. Prominent among this number are the Yellow Jacket and Salmon, owned by J. N. Manley and C. H. Williams, and the Mossback and Cora, owned and operated by J. H. Hilliard, John Coyle and W. P. Mount. In the latter locations nine mineral bearing ledges, ranging from three feet to six feet in width, have been found within the side lines of the claims and they are so situated that one opening will answer for all of them. The ore from these properties has been thoroughly tested and in every instance the returns have been most gratifying. Shafts have been sunk here and there along the veins that have demonstrated the surface existence of an ore body 300 feet in length. The character of the ore is the same as in all the other mines mentioned, but the great volume of mineral-bearing quartz in sight will ultimately bring these two properties into prominence in the mining world. It is a safe prediction that the time will come when the Mossback and Cora will contribute largely to the gold and silver output of the northwest, but capitalists must become identified with their development to bring about a realization of this prediction. Those who are in search of mining investments could not find a more encouraging field to operate in than the Greenhorn country. If the claims above mentioned were in any of the more favored mining districts they would long ago have been pouring their wealth into the channels of trade and a lively, prosperous camp denoted on the map.

Next season will be one of great activity throughout this entire district, and if indications are a safe criterion to be governed by, many valuable properties will be opened up before the return of another winter. R. C. G.

Granite, Or., Dec. 25, '94.

Laboring in High Altitudes.

Some curious facts are brought to light on the capabilities of men to labor at high altitudes during the construction of the Peruvian Central Railroad. This line starts at Lima, and proceeding inland, reaches its highest point at the tunnel of Galeria, 15,645 feet above sea level. It is stated that men were able to do a fair "sea level" day's work as long as the altitude did not exceed 8000 to 10,000 feet above sea level; but beyond this there was a sudden falling off in the work of one-fourth to one-third up to heights of 12,000 feet, and at still higher elevations 100 men were required to do work easily done by fifty at sea level.

Mining in Nevada County, Retrospective and Prospective.

Written for the MINING AND SCIENTIFIC PRESS by SAMUEL BUTLER.

It is customary for the careful and diligent man of business at the close of the year to sit down and balance up his accounts. In a dispassionate manner he ponders over his business and financial accomplishments during the year. He is retrospective, and carefully reviews the past. His future actions are guided in a great measure by his past experience. It is true that he may anticipate emergencies during the year on which he is just entering, and with the instinct of the true business man he makes proper provision for the same. But, nevertheless, he is almost entirely governed by past failures and successes.

The object of this writing is to take a calm and dispassionate retrospect of the past and to make some feeble suggestions relative to the future of mining in Nevada county. In doing this my words and opinions will be influenced to a great extent by what we have accomplished in the past through the different systems of mining in vogue here. This is the only chart we have by which to measure the future extent and prosperity of our great industry.

Nevada county bears the proud distinction of being the banner gold-prodneing county of California. Other counties have attempted to compete with her in the race for snpremacy, but when the yearly productions were put to the keen analytical test the disparity was very obvious. The suppression of hydraulic mining was of more serious consequence to Nevada than to any other couuty in the State. A careful estimate reveals the fact that through the inhibition of this system of mining this county was deprived of an annual revenue amounting to $3,750,000. The total production of our hydraulic mines up to the time of the suspension of operations through the decrees of the courts aggregated the magnificent sum of $112,000,000. The great injury received must therefore be apparent to all intelligent minds. But in spite of this disparagement we have continued at the head of the procession, and have always been found in the vanguard of progress. Our mines have been developed more successfully and to a greater depth than the mines of any other section of the State. No similar area in the world has paid more magnificently, considering the amount of capital invested, than that which comprises Nevada county. But there is yet room for judicious investment, the only thiug necessary to success being capital. "Money makes money," and without this essential requisite the speculator cannot succeed more successfully here than elsewhere.

The year 1894 dawned more auspiciously in this county than any previous year since the prohibition of hydraulic mining. The skies were exceedingly bright. Success beamed in every town, village and hamlet in the county. The anticipated resumption of hydraulic miuing aud a marked improvement in quartz mining imparted enthnsiasm to every resident. The previous year—1893—had witnessed the most disastrous financial depression ever recorded in American history. Gloom and depression were everywhere prevalent. But notwithstanding this fact and while the panic was ravaging the country from Maine to California, causing disaster wherever it entered, onr people viewed the result with almost stolid indifference, secure in the knowledge that while other industries were languishing and being forced to the wall through the great depression, our prime iudustry was rapidly increasing in extent and in the amount of production. Congratulations on the enjoyment of such an era of prosperity while the rest of the world was being degraded through commercial and financial depression, were very nnmerons. In my correspondence to the PRESS at that time I referred to the prosperous era in the following language: "The prospects for quartz mining were never brighter than at the present time. Increased interest is manifested by outside capitalists, and we predict for the year 1894 an era of nnprecedented prosperity."

During this year the North Star mine increased its output by over $100,000. Most of the other large mines—the Maryland, Omaha Con., Empire, W. Y. O. D., Champion, Providence, Nevada City and Monntaineer—were producing exceedingly well. They were being operated on sonnd business and financial principles; but a check to this unequalled prosperity came all too snddenly. It came in a manner, too, which sent terror to thonsands of uoble and courageons hearts. On the evening of Jannary 9th the protracted shrill of a mine whistle aronsed the residents and betokened danger. Investigation proved that a fire had started in the changing room of the Maryland mine and had qnickly commnnicated its deadly flames to the buildings adjacent thereto. For a while it seemed as thongh the entire property wonld be annihilated by the conflagration. Only the mill was saved of the surface bnildings. Even the shaft was mntilated for hundreds of feet. This was a misfortnne which the owners of the Maryland could illy afford to bear. They had only been in possession of the property a few months and had paid abont $70,000 of the purchase price when this calamity befell them. They had secnred the property after long and costly litigation, and for a time there were doubts as to their ability to rebnild. Previons to this time the Maryland, then known as the Idaho, had worked uninterruptedly for twenty-eight years. In that time $12,000,000 had been prodneed. Employment was given to 200 men, the mine was producing exceedingly well and fortune seemed to smile on the fortunate owners. The throwing out of employment of such a large number of men was an affliction which Grass Valley could not lightly bear. She was suddenly deprived of a revenne amounting to $750 a day, and the depressing effect was evident.

"Misfortunes never come singly" is an old adage, as true, probably truer, in mining as in other professions. Almost simultaneous with the Maryland disaster came the closing of the Champion mine of Nevada City. An injunction was placed upon the Champion Company by the Wyoming Company, and operations were entirely suspended. The latter company contended that the former was encroaching on its ground and they were determined to settle the difficnlty by judicial proceedings. The closing of this mine greatly affected the activity and prosperity of Nevada City. The Champion was one of the largest and most prodnctive mines in the county, a regular dividend payer and employed 150 men. It had been reopened and worked under great difficulties, causing the ontlay of an immense snm of money to put it on a paying basis. The company was just begiuning to realize the benefits which always accrue from capital judiciously invested, and the town was just emerging from the siege of depression which had hovered aronnd since the snppression of hydraulic mining, when this clash came. But the law is uncompromising, and this mine was destined to remain idle several months, much to the detriment of business and the prosperity of the town.

With the beginning of March a decline in the production of the North Star mine was strongly perceptible. This mine had increased its outpnt the previous year, as already stated, by over $100,000. A "crossing" was encountered in the 1800-foot level, the appearance of which nonplussed the owners and several mining experts who examined its peculiarities. As depth was attained, the "crossing" continued and became more formidable in size and the character of the rock which composed it. It was evident that nnless the "crossing" changed its course, and took a more westerly dip, it would seriously affect the ledge and limit the product of the mine. These fears were realized, and by the end of the month a reduction in the force of men, which was then 200, was made. This added denseness to the gloom overhanging the city from the suspension of the Maryland mine. The company continued to reduce its working force nntil in September nearly all of the 200 miners employed were discharged. Only a few prospectors were retained to try and unearth some new snbterranean riches. The company, evidently discouraged through the loss of the rich deposit of ore which had paid so magnificently, decided to abandon the mine entirely; bnt they shortly after reconsidered the matter of closing the mine, and there are now about one hundred tribnters at work there. It is to be hoped that they will snceeed in discovering a new "lead" which will retrieve the prestige of this famons mine and make it as prosperous as in days of yore.

In August the Centennial mine, which had been reopened by a company composed chiefly of Sacramento business men, superintended by A. W. Stoddart, suspended operations. This incident was only serious in so far as it apparently blighted the prospects of one of the most promising mines in Grass Valley. There were only a few men employed by this company, and they were working under the contract system. The men who were most deeply interested in the property claimed that they were nnable to meet the obligations of the mine, having to depend on their current business for financial snpport; bnt the great railroad strike so seriously affected their business that they were compelled to abandon the property. The Centennial is destined to become a valuable and permanent property. The writer personally inspected it, and in his correspondence to this journal at the time stated: "The Centennial Company may be congratulated on the possession of a very promising property; and if they are wise in their day and generation, they will spare no expense to make the development of the mine rapid and complete." This statement still holds good, as little development work has been done since that time. This mine will not be permitted to remain idle long. It is by far too valnable a property to remain in a state of desuetude. From 1876 to 1882 a party of common prospectors extracted over $500,000 from the vein, which averages a foot in thickuess. The last ton of ore crushed before the mine was purchased by the Sacramento syndicate paid $35.

Up to this time we have ouly written of the reverses experienced by the mining industry in this county. I have faithfully portrayed the dark side of the picture, and the most unpleasant part of the task is over; but as every cloud, however black, is supposed to have a "silver lining," so there is a bright side to the mining elements here. There were occasious when the snn of prosperity aud encouragement wonld shed its effulgent rays and illumine the gloom. While we did not realize all that we anticipated, and while the Allison Ranch, Massachusetts Hill and Rocky Bar Hill mines were uot rehabilitated as we were led to expect they would be, still there were other developments which gave canse for encouragement and enthusiasm.

The most marked improvement of auy environment of the county occurred at the Osborn Hill. This famous hill will eventually become one of the richest sections of Nevada county. The mines that have been reopened on this hill have paid immensely on the capital invested. The attention of capitalists is being constantly directed to this section. In the early days this hill was a bee-hive of industry, and now that its intrinsic value has become known we may anticipate remarkable improvements. The Osborn Hill is notably the most successful of the old mines which have been resuscitated. At a depth of 450 feet it produced $2,000,000, yet it is richer to-day than it ever was. It is one of the most productive mines in Grass Valley and employs a large number of men. During the past year the company has erected a new mill, increased the dimensions of its hoistiug works and the capacity of the machinery therein contained. It now gives every indication of being a valnable and permanent property.

The Electric mine, too, is situated on this hill close to the Osborn Hill mine. Many important developments have occurred there during the past twelve months, and the present prospects are very flattering. A mill has been erected and substantial hoisting machiuery constructed. The last ore extracted paid $50 per ton—a very rich vein considering the cheap facilities for milliug. On the same hill is the Conlin mine, which is rapidly making strides on the highway to prosperity. Much is expected of this property when it is properly developed. The Daisy Hill mine is situated in close proximity to the above mentioned mines. It promises to be a remnnerative property from the start. It has been reopened during the past year and worked in a manner which reflects great credit on the owners. A vein of ore twenty-one iuches thick and averaging from $30 to $50 per ton has been nncovered. A substantial hoisting and pumping plant has been erected, and the mine is lighted by electricity throughout.

The Merrimac has also been reopened during the past few months under the superintendency of L. P. Goldstone. Much may be expected from this source, as the mine has produced some rich ore during former workings. The South Idaho mine has made considerable progress in the past year. The last crushing of ore extracted averaged $200 a load.

In Nevada City the progress has been no less marked and eqnally gratifyiug. Several abandoned properties have been rehabilitated and give evidence of becoming valuable and permanent. The feature of greatest significance to the community is the purchase of the Wyoming mine by the Champion Company. This disposes of the dispnte involved in the suit brought by the Wyoming Company to restrain the Champion Company from trespassing on their property. This consnmmation is fortunate for the bnsiness interests of the town because the Champion Company purchases all its materials from local business honses. These properties will be developed ou a large scale in the coming spring. Other mines have been reopened, notably the Contact, Col. R. Clark, Home aud Reward. Some of these mines have produced remarkably well in former years, and they are being finely equipped with modern appliances, which indicates a long lease of life so far as good intentions are concerned. Most of them are under careful and experieuced management and will undoubtedly become valuable acquisitions to the town. The gravel mines have made a very favorable showing during the past year, especially the East Harmony and West Harmony, and they are expected to maintain their equilibrium during 1895.

And now I wish to refer to the prospects of the mining industry in Nevada county, as viewed from its present condition. We enter the year 1895 with a feeling of confidence. It is true that the production of our mines for 1894 will be less thau for the year previous. The reasons for this falling off have already been given. Most of the causes which led to the reduction were nnavoidable, such as the closing of the Champion mine, the Maryland disaster and the "crossing" encountered at the North Star. These events occurred without having "cast their shadows before." Some of the mines newly opened have compensated in a certain measure for the loss sustained through the suspension of some of the older mines. But it will take a number of small mines to equal the productiou of the North Star alone, which in 1893 produced in round numbers $335,756.

We confess we have bnt little faith in the immediate resumption of hydranlic mining. The immense benefits which would accrue to this county through the complete resuscitation of this system of mining can ouly be estimated by those who witnessed the perennial prosperity during the halcyon days of hydraulicking. We believe that American skill and genius will devise some means, in spite of the persistent opposition of the valley, whereby hydraulic miniug may be resumed without injury or detriment to farming interests. We believe that the miners

will ultimately triumph. Bnt the legal obstacles are so great and numerous at the present time that we do not anticipate mueh increase from that source, although several mines have heen given permits to resume operations. We must still rely on our quartz mines for the maintenance of our position as the leading gold producing region of the State.

It is my intention to point out—so far as my knowledge of the mines of this county permits me, and without going into detail as to my reason for so doing—where we are likely to derive an increase in our revenue. In Grass Valley the older mines are all in good condition and producing steadily. It is conservative to assert that some of them are "looking" exceedingly well—better, probahly, than they have appeared for several months past. This is especially true of the Maryland, Omaha Con., Empire, W. Y. O. D., New Orleans and Pennsylvania mines, which we regard as the oldest and most substantial in this district. Marked improvements have heen noticed in all these miues within the past few weeks, and an increased output may be anticipated in the near fntnre. The Peunsylvauia Company is just heginning to reap the reward of patieut and persistent prospecting. They have managed to keep their heads ahove water for the past six years and now they are heginning to swim. From the Osborn Hill environment we expect splendid developments dnring the coming year. Up to this time the Oshorn Hill mine has, in a great measure, heen doing preparatory work. They are now ready to work the mine on a large scale and we predict a great increase in the production of this mine. The same must be said for the other mines situated on this hill. The Electric, Daisy Hill and Conlin mines are in a position where they can he relied on to add materially to the gold producing capacity of Grass Valley. Then there is the Rose Hill mine, which has been honded by a company of Kansas capitalists. This mine has produced over $100,000 at a very superficial depth. The gentlemen who have possession of the property are capitalists of meaus and they are so highly pleased with the prospects that they have announeed their intention of developing it on an extensive plan.

The Kate Hayes mine is situated on the hill whose name it bears. In the '60s it was a noted mine, although uot worked to auy great depth. It is in a locality which guarantees the development of a splendid mine. If the mine is properly worked—aud we have reason to think it is under eapable management—it will prove a divideud-payer hefore the expiration of 1895. The South Idaho is another of the mines that is full of promise. The proprietors, who are mostly local men of limited means, are pegging away in the hope that they will eventually develop a large and productive mine. These mines, which are nearly all new, in company with the Merrimac, Slate Ledge, Wisconsin and several others, are expeeted to show a large increase in their production during the coming year.

Rumors are afloat to the effeet that James D. Hague has signified his intention to work the mines recently purehased by him on the Massachusetts and Rocky Bar hills in the spring. It is impossible to conceive the object of sueh derelietion on the part of the owners of these mines, considering the rich mineral belt in whieh they are loeated. The only reason to be assigned is that the company represented by Mr. Hague is waiting until cheaper motor power is iutrodueed—for it is impossible to convey water to these mines for motor power—which is a very important feature in developing mines on an extensive scale. If the proprietors of the Allison Raneh are sineere in their statements, that mine will also be reopened in the spring. We eannot grasp the possibilities of this mine when it is properly developed. It has not heen operated for over thirty years, bnt when it was worked it produeed $3,000,000 at a depth of 200 feet. The resuseitation of the Allisou Raneh would give a new lease of life to the village whose name it is known by. It is also stated that the famous Gold Hill mine is to be reopened in the spring, which is very gratifying news to all Nevada countyans.

In Nevada City the largest increase is expeeted from the Champion-Wyoming mine. No more enterprising company than the Champion ever operated in this eounty. They enter into all their transactions with a vim aud energy deserving of suecess. They have unlimited means and a rich property. Their future plans have uot yet been diselosed, but it is gratifying to know that this important mine will not suffer in the coming year in the same manner as it has done this year through litigation. It will undoubtedly treble its output in 1895. It is now recognized as one of the bulwarks of the mining industry here. The purehase of the Wyoming property refleets great eredit on the Champion Company and exhibits a strong business sagaeity. It is cause for eongratulation in Nevada City, because hoth the mines will be developed jointly and under the same management.

The Mountaineer mine is steadily progressing without the hlare of trumpets. W. A. Deunis, the superintendent of this mine, is one of the most competent and reliahle mining engineers that ever entered Nevada county, which meaus much. At the Mountaineer he has brought order out of chaos. He labored assiduously until he brought the mine into a high state of efficiency; from an almost worthless property into a dividend-paying mine. During the past year he found it necessary to reduce his working force for the purpose of prospecting certain parts of the mine which had been previously neglected. He has succeeded in developing these abandoned sections, and the old force of men is at work again. We may expect an increase of production from this source in the eoming year.

The Providence and Nevada City mines, both large producers, still maintain their position among the leading mines of this town. Barring unforeseen events, these mines are likely to greatly increase their product during the coming year. Especially is this trne of the Nevada City mine. The purchase of the Mayflower mine by a company of capitalists represented hy Mr. Lane of Calaveras is considered a fortuuate ineideut here. This mine was owned by the Martin brothers of this city for a number of years, and was operated by them on a very meager scale. The transfer of the property indicates that it will he developed on a scale commensurate with its worth. The company is a wealthy one, aud, as soon as the weather permits, will make exteusive improvements on the mine. This will help to swell the increase in production everywhere prevalent. The new mines that have recently started will add materially to the wealth of the couuty. We cannot look to them for much of an increase in the near future, hut hefore the expiration of 1895, with proper preparatory work, they will become suhstantial properties. Quartz mining has received quite an impetus on the San Juan Ridge during the past year. In close proximity to the town of San Juan are some very promising prospects. They are located on the Boss ledge, which is said to be a veritable honanza. This vein is an immense deposit of gold quartz. Its correct width has not yet been ascertained, althongh it has been developed for eighty feet. A eompany of San Franeisco capitalists have recently organized to work a portion of this ledge. Should they prove successful, and we sineerely think they will, an interest in that section of the eounty will have been aroused that will result in material benefit to San Juan and the county as a whole. The Live Oak and Badger Hill mines are also situated on this ridge aud give evidence of becoming reliahle bullion producers. If development work in the quartz mines on the San Juan Ridge continues during the coming year, and suffieient capital ean be interested in their welfare, they will prove a valuable adjunct to the eounty.

I have eudeavored to faithfully diagnose the present condition of the mining industry of our eounty. I have made no attempt at exaggeration or to lend eolor to any of the statements I have made. Every assertion can be substantiated by a personal investigation of the properties ahove mentioned. I have suffered too much myself from ephemeral hooms, whieh have been concocted in the minds of reckless speculators, to delude miners and capitalists, to try and mislead others. Parties interested in Nevada county mines have always pursued a eonservative eourse, sometimes to the injury and detriment of their own interests. But from present indieations it is safe to assert that this eouuty is just enteriug on an era of genuine prosperity sueh as it has not been her good fortune to enjoy since the suppression of hydraulic mining.

Nevada City, Dec. 24, 1894.

Right Kind of "Salt."

Surprise and amusemeut were created among the offieers of the Mereur Mining Company yesterday by the report of Attorney Frew's testimony as to the "salting" of the mines reeently purchased by them in California. The gentlemen were inelined to admit that the best of experts ean be fooled by "salting," but they are at a loss to understand how it is that, if the mine really was doetored, the ore they have taken out sinee the purehase of the property has run higher in assays than that ou the basis of which they bought the mine. Two carload lots were taken out under Mr. Brown's direetion previous to the purchase aud earefully run through the mill under his supervisiou. Then, immediately after the purchase, Mr. Browu went to the mine again and took ont another earload lot to be brought to this eity for a test in connection with two kinds of mills, in order to determine whieh one eould be used to best advantage. All that ore was removed from the mine, as it were, directly uuder Mr. Brown's nose; yet it ran several points higher than the first two lots.

Messrs. Dern, Airis, Brown and others, therefore, are not made at all uneasy hy Mr. Frew's deelarations. They believe that the property has been tested, and that they have become owners of something of real value. Only a break in the weather is awaited before steps will be taken looking to the ereetion of milling and other improvements.—Salt Lake Trihuue.

M. WOLFF has a five-eolumn article in a contemporary arguing that the earth is uot an oblate spheroid iu form. He says its shape is that of an elongated cone, and proves it—to his own satisfaction. The gentleman who recently destroyed the gravitation theory need no longer be lonesome.

Tuolumne County.

From Our Traveling Correspondent.

TO THE EDITOR:—Just below the junction of the North and Middle Forks of the Stanislaus river J. S. Suhlett of Murphys, Calaveras Co., is opening up a quartz mine with a ground sluice. His mine, the Chimey Rock, is abont half way up the steep mountain side. Here a stroug reef of granite crops and forms the hanging wall of his vein. This wall shows a skin of quartz rich in gold. The vein and footwall have been gronnd down by a slide a width of twenty feet. This matter Mr. Sublett is slnicing out to get at his vein. It is rich in gold, and in it are found pieces of the ledge two to four feet wide, all rich in visihle gold.

Adjoining this vein are several ledges that show very good rock and on which consideralle work has been done, but it is the Chimey Rock vein that he looks upon as his honanza. South of this lie the Col. Dorsey mines. Mr. Dorsey's working partner, Elliott, has bouded his interests, and it looks as though something might now be done with this group of mines. To the east the Star and a number of other mines have recently been honded by Eastern people, who are at work developing the same.

The Keltz, W. Sharwood of Soulshyville superintendent: The mine is steadily being developed by extending the drifts in from the mountain side. As the drifts get depth the quality and quantity of the rock increase in value and size, and the mine is in a more prosperous condition to-day than at any time past, with a hright future before it. The mill is now of fifteen stamps that are kept continuously dropping on the quartz from the six-foot ledge.

West of the Keltz and east of Columhia is the Ham and Birney, W. Sharwood superintendent. The vein's eourse is from hottom to top of a ridge 2000 feet high. The miue is developed by a series of drifts driven from the surface on the vein. The vein is ahout five feet in width and is in slate walls. The veiu is very flat and the baek seams immense. The vein ean be developed from base to snmmit by drifts to a depth of ahout 2000 feet, and as no sinking, pumping, hoisting or expensive timbering are required, the ore ean easily he mined and milled for not to exceed $2.50 a ton. There is a new ten-stamp mill that was started to dropping while I was at the mine. This mill is situated about half way down the mouutain side, and, while this mill has a high head of water, its waste water ean he used to run another mill at the base of the hill. The mill is of Mr. Sharwood's designiug, and in it are a number of features that will reeommend themselves to millmen. The front plate in the battery slopes up to and against the screen, with no strips on the inside of the screen. This eauses the water to flow up and against the screen iu an even, continuous play, aud thus add to the discharge. Just above the sereeu is a narrow board, which, when removed, enables the millman to see the condition of the battery and to fish out any floating wood. Above this is a sheet of iron with wooden frame. The whole front of the battery can be removed hy simply turuing a few huttons. In front of the screen is a narrow plate. Below this the ore flows into a narrow hox, and from it through pipe to the plates. These pipes are about two feet long, thus leaving a space for the millman when cleaning up. The plates are hung on rods at the lower ends, so that they can be given any desired piteh. The situation, water power, size and value of the vein make the mine a good proposition.

Old Tnolumne, R. C. Davis of Colnmbia, snperintendeut: The mine is northeast of Columbia, on the south fork of the Stanislaus river. The drifts are now in 800 feet on the old and 1700 feet on the new, and they are still driving for the vein. In the old drift the vein is about four feet of $10 ore. Five stamps are now droppiug and five more will soon he started. The mine is an old property, but had been idle for some time. With the exeeption of one or two small claims there is now uothiug doing in gravel in this ouce famous section from Columhia to Sonora.

Summersville.—Eureka Con., better known as the Old Dead Horse, is running steadily, with Mr. C. H. Thomas as superintendent. The shaft is now down 1360 feet, which makes it the dcepest mine in the eounty. The vein runs from four to five feet in width. At this depth Mr. Thomas mines and mills for an average of $2.50 a tou by the year, and has done it for $2.25, which is very elose for shaft work. The mill is of twenty stamps and the whole plant is operated by water power. Just south of the Eureka John Rhuhe has taken hold of the Lady Washington, and with his usual luck, or rather knowledge, has shown up a shoot of good ore. The Seminole is also said to be looking well, but as the operators of these two were not on the mines at the time of my visit, I eould not get any reliable information eoncerning either.

Northeast of Summersville is the Cherokee distriet. Ou the north extension of the Dead Horse is the Laura, W. Long, superintendeut. The company has put dowu a shaft 400 feet and drifted 850 feet north on the four to five-foot vein. The superintcudent is running to catch the junction of the Car-

lotta and Pennsylvania with their vein. As both these veins are known to be rich, he has every reason to expect a rich shoot at their junction. About 1100 feet north is the old shaft, the ore from which prospects well. Mr. Long has averaged 100 feet a month in sinking and drifting in granite with a force of but six men. This mine is in the Cherokee district. Mr. Leachman has had the Carlotta and Pennsylvania pumped out for inspection. The Carlotta shows fifteen inches of $35 to $45 ore, while the Pennsylvania, adjoining, shows two feet and over of $10 ore. The mines are the property of Mr. Fred Sutton of Sonora, and are as good an investment as can be found in the country. Mr. Sharwood of Soulsbyville owns the Ponto Fino, which is just south of the Carlotta. This is a small vein of heavily mineralized ore, a property that would delight a Colorado operator who knows what can be done with small veins of good ore. If these three mines were consolidated they could furnish sufficient sulphurets for their own chlorination plant, and thus by working the ore on the ground could be made a very valuable property.

Soulsbyville.—The Old Soulsby, W. Sharwood, owner: The shaft was put down 800 feet and a drift run south, and above this three million dollars was stoped out. When this was exhausted, a drift was run north; and as no ore shoot was encountered, the mine was shut down. South is an old shaft, in which, at eighty feet, the early miners came to a "throw" in the vein and stopped. The vein matter here went $100 a ton. Pieces of ore found in the old dump show visible gold very freely and prove the value of this ore shoot. It is only necessary to continue this shaft on down and crosscut to get the same shoot; and when sufficient depth is attained to drift north under the old works, and get the north shoot, there is a large area of virgin ground, and the Old Soulsby only needs to be reopened to be added to the list of the big mines of the State.

The Oaks Con., C. E. Shafer, superintendent: This is the old Black Oak mine. The present owners have reconstructed the hoist and mill, and everything indicates that the mine will now begin a chase to show what there is in it. The superintendent is putting down the shaft on a nine-foot vein, carrying four per cent of high-grade sulphurets in addition to the free gold. The ten-stamp mill is kept dropping on the ore taken out in sinking above. Everything goes to show that this mine is all that the writer, in the past, has claimed for it.

North of this section on Sullivan creek is the Bellview or Hyde mine, A. M. Mackdonald superintendent. The mill of ten stamps is idle, while the shaft is being put down 200 feet by contract.

Sonora.—This is a very pleasant place for a residence; and being centrally located, makes miniug in this county all that could be desired. The volume of business in Sonora is not as great as would be expected from the extent of mining and agriculture. This is due to the fact that all the old camps, which are scattered all over the county, have large stores that do a thriving business. At Sonora the Golden Gate is still in the hands of the affable receiver, Mr. R. B. Lane, pending litigation. The shaft is now dowu 660 feet, with levels run 800 feet north and 500 feet south. The veins' value is almost entirely in the sulphurets, which are high in grade. The mine is equipped with ten stamps and chlorination works, all run by water power. The Old Bouanza mine has "gone out of bonanza," and is resting on its laurels, while the lucky superinteudent, D. R. Oliver, is hunting for a big pocket in the Oregon mines. The pocket miners are at work throughout the county, but of late have struck no big pockets.

Jacksonville.—Mammoth mine, J. F. Bluett superintendent: This property, 2200 feet in length by 300 in width, is now the property of the Mammoth Mining Co., owners of the Sierra Buttes mines. The mine is situated on the east bank of Woods creek, just north of its junction with the Tuolumne river. The veiu is the mother lode, which is being developed by three crosscut tunnels, the lowest of which will tap the vein 500 feet deep. In one of the tuunels the vein is being crosscut, and is now twenty feet wide and the wall not reached. The ore shows visible gold, and the owners are feeling very good over their purchase. A mill site for twenty stamps is now being graded. Additional stamps will be added as the mine is developed. The mine has its own water system, and the future looks very promising for this English company, which, under Mr. Wm. John's management, have steered clear of the breakers that so many of these English companies wreck on, and in their Plumas-Eureka, Sierra Buttes, Uncle Sam and now Mammoth have some of the best mines in the State.

Just north of the Mammoth, on the Eagle is to be found one of the strongest croppings on the mother lode in California. It is remarkable in its height, width and extent.

Quartz Mountain.—On the App the shaft is down 825 feet, with drifts run 225 feet uorth and 250 feet south. The drifts are now being extended.

The Miller & Holmes, E. A. Stent, superintendent: The south shaft is down 250 feet, with drifts run north and south, and crosscuts 140 feet west and 108 feet east. While I was at Quartz Mountain the superintendent received notice that the miue had been taken by the Napa Quicksilver Co.

The Golden Rule, O. S. Cressy and W. McGinn, proprietors: The shaft is now down 200 feet and will be put down to 250 feet, when they expect to strike an old shoot that milled about $10 a ton from a ten-foot vein. The mine has a ten-stamp mill.

The Juniper, Hunt & Landers, proprietors: This property has just been takeu hold of. The owners are taking the water out of the old 140-foot shaft. The ore from this shaft is said to have milled $14 a ton, in addition to the pockets.

The Dutch, A. Trittenbach, superintendeut: The drift is now being run north from the third level and is in about sixty feet on the hanging wall of the east vein. This drift will cut a known shoot to the north in about forty feet more. In the shaft the vein is about five feet wide of ore that samples from $21 to $42 a ton. The Dutch has all the veins of the mother lode and are but a few feet apart on the surface. In addition, there are a number of feeders, good, big ledges in themselves, coming in on both sides that have been so rich that they were worked as pocket veins. It is only a question of development with this mine, and once Mr. Trittenbach gets his property equipped and developed as he has planned, the Dutch will be the peer of auy other nationality, for "it has the stuff in it." All of the mines here mentioned are on the mother lode.

The Pine Ridge, Stent & McDougal, proprietors: This mine is about one mile west of the mother lode and runs east and west, making it a spur or feeder of the mother lode. The vein is from two to five feet wide, with a porphyry hanging wall and slate foot wall. The shaft is now down eighty feet. All the ore taken from the shaft has been milled, giving $14 to $23 a ton.

Jamestown.—The Gem mine, Henslee Bros., proprietors: This property is better known as the Harris mine. It is being worked by an open cut which, with water power, enables the owners to mine and mill with their ten stamps for $1.25 a ton, the $5.50 to $7.50 ore of the vein.

The Crystalline: This property is being developed under bond by the Black Oak Co. They have a crosscut in and drifts run on the lode.

Leaving the Crystalline, you drive north over the mother lode to the summit of a hill, where, looking down, the Rawhide miue with its numerous red buildings spreads out like a pauorama below you and suggests a military post or State institution iu the exteut, uuiformity of color, design and general neatness of the entire plant. The mill I have deseribed before; suffice it to say that it is a model in every detail and is a credit to the millwright who designed and constructed it. Since my last visit a chlorination plant of three tons a day capacity has been erected. This, too, is a model in every way, particularly iu its trim, well kept appearance. The hoist is in keeping with the rest of the plant, while the large boarding house with its porches filled with geraniums in bloom suggests more a summer resort than the customary barren mining plant. The affable superintendent, Mr. Nevills, informs me that the shaft is being sunk to the 600-foot level, while drifts have been ruu 250 feet north and south. The east vein averages ten feet iu width, while on the west a forty-five foot crosscut has not reached the walls. This mine has the reputation of producing the richest ore of any mine in the State; but, like other owners of good mines, Mr. Nevills regrets that it is uot policy to say anything about the ore values; and so while mining assessments, failures and frauds are glariugly advertised the good mines of the State are forced to keep their product to themselves, and in consequence the capitalists on the outside assert that more mouey has gone into than has ever come out of the mines, judging from what they see printed.

The Rawhide No. 2: This miue is the property of Mr. A. Hayward and adjoins the Rawhide on the south. Mr. W. Garrard, of the Gold Cliff mine at Angels, has recently put down a shaft on the north end of this mine and quietly remarks that "She only wants a shaft 600 feet to make her the equal of the Rawhide."

The Rappahannock, R. Chute, superintendent: This mine adjoins the Rawhide on the north. It is equipped with a good steam hoist and the shaft is now down 125 feet in the footwall. The vein in the air shaft prospects very satisfactorily and makes Mr. Chute confideut that he has but to get there to get it. Several mines to the north have recently been bonded and work will soon be commenced.

The Darrow mine, Darrow Bros. and Whitney, proprietors: This mine is about three-fourths of a mile northeast of the Rawhide aud about 1200 feet east of the Rawhide vein. The mine has been worked off and ou for the past thirty years and was once incorporated for $1,500,000. During the past year $19,000 was taken out by the expenditure of about $300. The vein is a mixture of slate and quartz about ten feet wide, and carries three per cent of sulphurets that assay $100 a ton. The owners put the average milling value of the vein at $10 a ton. They have now erected a water-power hoist aud will proceed to develop the mine. Iu clearing out the old shaft it became necessary to put a shaft into the footwall. This shaft threw out quartz which is "just lousy with gold."

Tuttletown.—The old Pat Mullen mine, just southwest of Tuttletown, has been secured by Mr. E. C. Loftus of the Golden Gate mine. He is engaged in driving a tunnel from Mormon creek aud shows very haudsome rock; it is good for a fine property.

Frank Grass and Williams are also starting a tunnel on their mine on the west branch of the mother lode.

The writer has endeavored several times to secure a map showing the situation of the various mines, the different mineral belts and the geology of the county, but has failed. In the higher elevations are the Sugar Pine mines. These were worked extensively years ago and were very rich. Below them follows the belt in the Dead Horse group. Adjoining come the cross veins in the Cherokee belt; then the Soulsbyville granite belt, while to the north are the Keltz, Ham & Birney, and other mines in the slate. Still on west is the Sonora belt, with the Golden Gate mine. To the south and north, extending to Columbia, is the pocket belt in the dykes and slates adjoining the limestone belt. Lower down and west the mother lode enters the county from Mariposa county at Jacksonville, and follows across to Quartz Mountain, Jamestown, Rawhide, Tuttletown, and crosses into Calaveras county at Robinson's Ferry. In the vicinity of Tuttletown are numerous pocket veins on Jackass Hill that have in the aggregate yielded large amounts. In pocket mining Tuolumne has stood at the head, with a production of $3,000,000 from the Bonanza in pockets. West of the mother lode are several strong ledges, while numerous feeders cross the country through this talc and serpeutine slate belt. As will be seen, the county is traversed by succeeding mineralized belts that extend from the plains to the higher altitudes in the mountains, giving it an extent of mineralized country not equalled by any county in the State, thus assuring the mining future of the county.

The mines in operation aud those in course of development will soon need an increased water system, and the present ditch owners should awaken from their Rip Vau Wiukle sleep to the condition of the present and prospects for the near future. There is nowhere a safer, more profitable or desirable investment than the purchase and iucrease of this water system. As you leave Tuolumne the last stopping place is the Chicken House at Tuttletown, where all mining men find an excuse for stopping. No matter how bad the weather, unfavorable the ventures or churlish the treatment received elsewhere, oue meal of the delicious fried chicken served here blots out all else and the traveler journeys on, singing "Here's to Old Tuolumne, and may her gold output and chicken crop never grow less." E. H. SCHAEFFLE.

Murphys, Cal., Dec. 19, 1894.

Quicksilver.

California has the only important quicksilver mines on the American eoutinent, but this industry in late years has had to contend with a number of uufavorable factors. The unprecedented decline in the value of silver bullion, and the consequent restriction of mining operations, greatly curtailed the demand; and the loss of the Chiua trade, for many years the chief support of the quicksilver market, was also a serious setback to oue of California's most important industries.

When a large number of deposits were being worked iu this State, aud the output resulted in low prices, California successfully outbid Loudon for the trade with the Orieut. But as the price of quicksilver declined to a point at which mauy of the small mines could not be profitably worked, the list was narrowed down and the annual yield fell off considerably. With a more limited yield, however, and such demands as were made on producers from New York, etc., the market recovered to some extent.

The average price in 1880 was $31 per flask, declining to $27.25 in 1883, and advancing to $53.25 in 1890. The present current rate is $37.

The largest annual production was 79,396 flasks, in 1877, and the largest number exported by sea and overland was in 1879, being 62,845. The highest price on record iu the San Fraucisco markets was $1.55 per pound, in 1874–5, and the lowest was 33 cents in 1879.

In November, 1874, a contract was made for the monthly delivery of 400 flasks for one year to the Bonauza mines at $1.50 per pound.

There was an increase in the export trade during the year. There were 3346 more flasks exported in '94 than in '93, but the value in '94 was but $541,380 as against $581,616 in '93, the prices haviug been lower last year.

The exports of the year were distributed as follows:

To—	Flasks.	Value.
New York	8,120	$243,600
China	4,600	138,000
Australia	100	3,000
New Zealand	10	300
Central America	804	24,120
Mexico	4,161	124,830
British Columbia	46	1,380
Canada	200	6,000
Japan	5	150
Totals	18,046	$541,380

A recapitulation of the shipments by both sea aud rail duriug the year is as follows:

	Flasks.	Value.
By sea	18,046	$541,380
By rail	10,933	395,400
Totals	28,979	$936,780

Scientific Progress.

A Chemical Curiosity.

Among the various uses to which electricity has been put since its cheap production by the modern "dynamo" has been secured is the reduction of metallic ores or compounds in one or another form of the "electric furnace." The production of aluminum on a large commercial scale is the oldest and best known of these. There are, however, several cases in which the separation of the single element is not secured even in the electric furnace, but in which the element desired, while parting with its former companions, insists upon a substitute, and takes the same from the carbon electrodes or lining of the furnace, or from carbon mixed with it. This is the case in the manufacture of "carborundum," which is a compound of silicon and carbon, formed by heating silica and carbon powder in an electric furnace. This compound has reached a large commercial application, by reason of its extreme hardness, which makes it a very superior substitute for emery or corundum, as a cutting and polishing material. The latest development in this direction, however, is seen in the calcium carbide, which is prepared by heating in an electric furnace a mixture of lime and coal dust. The metallic calcium liberated by the action goes at once into combination with carbon to form a carbide, which is a mineral body of remarkable properties.

In appearance, when in masses, it somewhat resembles the mineral serpentine, being of a greenish-gray color and crystalline fracture, with a luster like feldspar. If a few drops of water are thrown on this mass of seeming rock, gas is given off, which, if ignited, burns with a brilliant flame; and, by continuing from time to time to sprinkle the rock with water, it will be made to blaze continuously as though it was being sprinkled with some very volatile and inflammable oil. If a fragment of the mineral is thrown into a glass of water, a rapid evolution of gas results, which may be ignited, and will continue to burn until the mineral is exhausted. The cause of these actions is that the calcium carbide in contact with water forms calcium oxide and acetylene gas, the oxygen of the water combining with the calcium to form calcic oxide or lime, and the hydrogen of the water combining with the carbon to form acetylene. It is proposed to use this calcium carbide for local gas machines. A charge of the mineral is placed in a closed vessel into which a regulated supply of water is admitted. A little water entering forms a quantity of gas whose pressure shuts off the water; but, as the gas is used up, more water comes in to renew the supply. What may be the commercial value of this material cannot be at present determined, but it is certainly a great chemical curiosity.

Four Hundred Degrees Below Zero.

Four hundred and twenty-four degrees Fahrenheit below zero! Just what this means it is almost impossible to imagine, and yet it is one of the temperatures which have been reached and used in laboratory research, and has been made the subject of some highly interesting experiments and explanations by Prof. Dewar, before the British Royal Institution. Four hundred degrees below zero is not an everyday temperature, nor can it be reached by more every-day means than the expansion of liquid air, which latter Prof. Dewar has succeeded in producing in comparatively large quantities, and in storing by novel and ingenious methods, to be used as required in the study of matter at abnormally low temperature, exactly as a spirit lamp or a Bunsen burner is used in studying the properties of different bodies at the higher temperatures.

The tensile strength of iron at 400 degrees below zero is just twice what it is at 60 degrees above. It will take a strain of sixty instead of thirty tons to the square inch, and equally curious results have come out as to the elongation of metals under these conditions. It was an idea of Faraday that the magnetism in a permanent magnet would be increased at very low temperatures, and experiments with comparatively low temperatures had rather negatived Faraday's suggestion, but Prof. Dewar has completely verified the opinion of the famous savant, having shown that a magnet at the extremely low temperature made possible by the liquid air had its power increased by about 50 per cent. Very low temperature was shown also to have a remarkable effect upon the color of many bodies. For example, the brilliant scarlet of vermilion and mercuric iodide is reduced, under its influence to a pale orange, the original color returning with the rise of the temperature. Blues, on the other hand, are unaffected by cold, and the effect is comparatively small upon organic coloring in matters of all tints.—Cassier's Magazine.

The New Constituent of the Air.

Lord Rayleigh's curious discovery is that the gas obtained by taking vapor of water, carbonic acid, and oxygen from common air is denser by $\frac{1}{230}$ than nitrogen obtained by chemical processes from nitric oxide, or from nitrous oxide, or ammonium nitrite, thereby rendering it probable that atmospheric air is a mixture of nitrogen and a small proportion of some unknown and heavier gas. Rayleigh and Ramsey (who joined in the work at this stage) have since succeeded in isolating the new gas, both by removing nitrogen from common air by Cavendish's old process of passing electric sparks through it, and taking away the nitrous compounds thus produced by alkaline liquor; and by absorption by metallic magnesium. From this occurrence Lord Kelvin deduces "a fresh and most interesting verification of a statement which I took occasion to make in my presidential address to the British Association in 1871: 'Accurate and minute measurement seems to the non-scientific imagination a less lofty and dignified work than looking for something new. But nearly all the grandest discoveries of science have been but the rewards of accurate measurement and patient, long-continued labor in the minute sifting of numerical results.' The investigation of the new gas is now being carried on vigorously, and has already led to the wonderful conclusion that the gas does not combine with any other chemical substance which has hitherto been presented to it."

A Big Copper Deal Predicted.

Chicago advices say: An international deal in copper is likely to be perfected soon. Ever since the smash-up of the great corner in copper which was created by a French and English syndicate three years ago speculators have been figuring how to put through some such scheme. This time it is a combination of French capital which will engineer the scheme. Representatives of the combine were in Chicago several days ago and were joined here by John Dempter of Glasgow. Arthur Turnbull of New York, who is interested in the American end of the deal, also came on here, and yesterday this party left for the West. Their mission, it is said, is to confer with the owners of the immense Montana and Arizona properties.

The scheme of the syndicate is to get the owners to cut in two the output and not exceed 5,000,000 pounds a month. This would bring down the figures of the Anaconda properties to those of the Hecla and Calumet mines. All the arrangements have been made for the carrying out of the deal, and it only remains for Marcus Daly to give his consent. He is a difficult man to deal with, but the promoters profess to believe that they can afford to offer a big inducement.

A thoroughly competent Amalgamator wants a position where mine and mill assaying is required. References given. Address Box D, this office.

All kinds of tools. Fortune for the driller by using our Adamantine process; can take a core. Perfected Economical Artesian Pumping Rigs to work by Steam, Air, etc. Let us help you. **THE AMERICAN WELL WORKS,**
Aurora, Ill.; Chicago, Ill.; Dallas, Tex.

RUPTURE!

IT has been considered by the medical profession that hernia—commonly called rupture—was incurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But DR. J. C. ANTHONY, of 86 and 87 CHRONICLE BUILDING, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patient no pain, and those living near enough do not lose any time only while in his office once or twice weekly. He guarantees every case he treats, and does not ask a man for a dollar unless he cures him, so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medical College, of New York City.

The Explorers' and Assayers' Companion.
A Third Edition of Selected Portions of the "Explorers', Miners' and Metallurgists' Companion."
By J. S. PHILLIPS, M. E.
The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay has been kept as free from formulæ as possible. The work is written for practical men, and all the explanations and discriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.
Price $6.00 postpaid. Sold by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco

WHEEL

CASCADE WATER WHEEL

Adapted to all heads, from **30 FEET TO 2000 FEET.** Our experience of **33 YEARS** in the water wheel business enables us to suit every requirement of water power plants. Send for illustrated pamphlet. This new wheel has given an unequaled Economy in Water.

JAMES LEFFEL & CO. Springfield, Ohio, U.S.A.

DEWEY & CO., 220 Market St., SAN FRANCISCO,

PATENT SOLICITORS.

ESTABLISHED 1863

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S.F.

Rose's Complete Practical Machinist.

19th EDITION GREATLY ENLARGED.

JUST READY.

The Complete Practical Machinist: Embracing Lathe Work, Vise Work, Drills and Drilling, Taps and Dies, Hardening and Tempering, The Making and Use of Tools, Tool Grinding, Marking out Work, Machine Tools, etc. By Joshua Rose, M. E., author of "Mechanical Drawing Self Taught," "Modern Steam Engines," "Steam Boilers," "The Slide Valve," "Pattern Maker's Assistant." Illustrated by 385 engravings. 19th edition, greatly enlarged, with new and valuable matter. 12mo., 504 pages. Price, **$2.50. By mail, free of postage, to any address in the world.**

ABSTRACT OF CONTENTS. Chapter I. Cutting Tools for Lathes and Planing Machines. II. Cutting Speed and Feed. III. Boring Tools for Lathe Work. IV. Screw Cutting Tools. V. Lathe Dogs, Carriers or Drivers. VI. Turning Eccentrics. VII. Hand Turning. VIII. Drilling in the Lathe. IX. Boring Bars. X. Slotting Machine Tools. XI. Twist Drills. XII. Tool Steel. XIII. Taps and Dies. XIV. Vise Work: Tools. XV. Fitting Cutting Rods. XVI. Milling Machines and Milling Tools. XVII. Grindstone and Tool Grinding. XVIII. Lining or Marking out Work. XIX. Machine Tools. XX. To Calculate the Speed of Wheels, Pulleys, Etc. XXI. How to Set a Slide Valve. XXII. Pumps. Index.

Price $2.50 by mail, free of postage, to any address in the world.

A circular of 4 pages, with specimens of the illustrations, showing the full Table of Contents, will be sent free to any one furnishing his address.

Our New and Enlarged Catalogue of Practical and Scientific Books, 91 pages, 8vo., and our other Catalogues, the whole covering every branch of Science applied to the Arts, sent free and free of postage to any one in any part of the world who will furnish us with his address.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

THE KENNEDY—JACKSON DISTRICT.—*Record:* Superintendent Parks of the Kennedy is a great prospector. He constantly has men at work opening up new ground and prospectiug the ledge, no matter how well the mine may he paying at the time. The south shaft has heen sunk 200 feet recently, making it now 1750 feet with a seventy foot sump, vertical depth or nearly 2500 feet length of shaft. Sinking is soon to he commenced at the north shaft to carry it dowu 200 feet, that is to the same depth as the south shaft. During the past week some repairs to the north shaft preparatory to heginniug sinking have tied up the north skips and the greatest portion of the work has heen done at the south shaft. As soon as the sinking is completed at the north shaft they will crosscut to the ledge, counecting the crosscuts hy a drift. The additional depth of the Kennedy shaft makes it the deepest mine working on the mother lode, and prohahly the deepest in the State.

Trinity.

CHLORIDE QUARTZ MILL CRUSHED.—James and Charles Gilzean have leased the Bailey mines at Dedrick and intended to stop at the mines and work through the winter, hut gave it up as the snow was getting too deep and was sliding in all directions. All around the cahins the snow was eight to ten feet deep. On the 20th ult. says the *Journal* a snow slide started across the creek, surged up the hill and struck the little house covering the Pelton water wheel which runs the Chloride quartz mill, knocking that down. The mill itself then fell but did not slide. The snow covered everything hut the mill was not much injured. This is the third time that this mill has heen wrecked hy suow. Once at Deadwood wheu Ballou owned it aud once in the winter of '91 and '92, when a snow slide swept it from its preseut site and spread it along the creek and ravine for a mile.

ARIZONA.

CHERRY CREEK.—*Courier:* D. E. Dumas has heen in town for the past few days paying out money made from ore which he arrastraed from his gold claims on Cherry creek. The ore yielded $25 per ton and the concentrates contain at least $100 or more per ton. A concentrator is badly needed for that camp. He has a vein of from two or three feet of pay ore in his mines. Three quartz mills will prohahly soon he in operation on the creek. The De Kuhn mill, leased by Major Watts, the Conger mill and the Barshaw mill.

Messrs. Sines and Smith have struck it rich in their Cherry mine and have exposed, near the surface, a pay streak twenty inches wide which pans not less that $200 per ton gold. A shipment of several tons of ore from the mine is now at the sampler.

TIN MINE.—Cap. Jones, a prospector, has located a tin mine 125 miles from Yuma and fifteen miles from the Colorado river. The ore is a grayish hlack and specimens sent to various cities show that the ore is about ten per cent tin. The Temescal mines run one aud one-half per cent tin. The ore lies in a hed, apparently of several hundred acres, and appears to have slid dowu a mountain. It is mixed with red and yellow oxides, and is covered with layers of quartz and talque.

ALASKA.

At Seward City, the additional twenty stamps are finished. The Bear mine tunnel has heen driven 135 feet, and has now 310 feet more to go to tap the ledge at a point ahout 300 feet under the old workings. A winze is heing sunk on the ledge to connect the two tunnels run formerly hy the German company in the Bear mine, and the ore has increased in grade.

At the Comet miue the hottom level is driven ahead continually in high-grade ore that assays more than that taken from the top levels. One hundred feet from the face of the bottom level a crosscut is going ahead to tap Comet ledge No. 2, located farther up the hill. This will furnish extensive stoping ground. At present the Comet mine has a finer showing of ore in sight than at any time in its development. Gold hullion shipments are made from the mill twice a month.

THE YUKON COUNTRY.—Writing from Hunter's creek, in the Yukon River region, to the *Record*, a miner says the stream is 150 miles above the mouth of the Tananah river and 750 miles helow the mouth of Forty Mile. Fourteen white men are working there on the hars with very good success. The hedrock so far as known is from three to six feet under surface. The miners have averaged from one to one and one-half oxs. per day, and of course the pay will increase as they get their claims opened up.

During the summer the miners hecame alarmed, fearing they wonld run out of provisions, and stationed a watch on the hank of the Yukon to hail any passing hoat with supplies. Healy & Hamiltou's steamer came along and supplied the camp with $3,000 worth of grub, the miners planking down the gold dust for the same.

Hunter's creek is ahout fourteen miles in length. The rich discoveries on the Yukon this year are the following creeks: Ahout 200 miles helow Forty Mile are four rich creeks, named the Independent, Miller, Mastodon and Mammoth. It is said that the creeks exceed in richness the former discoveries on Forty Mile or Miller creeks, the miners so far averaging from two and one-half to three and one-half ozs. per day. Some miners here have taken up two and three claims though it is not likely that more than one can be held, hut on account of the great richness of the ground the men are much excited. These claims are 500 feet long and run the full width of the creeks, which pay the full width. This is the reason this creek is so much more valuahle than others. Hundreds of claims just as good as those staked out are still opeu for location. Claim operators are offering $16 a day for men with none to he had at that rate of wages. Well-posted miners say there will be work for 1000 men for the next ten to fifteen years. There is an ahundance of water with a good fall. Bedrock is nowhere more than five feet helow the surface. There is already a heautiful townsite located on the hanks of the Yukon and ahout 100 houses in course of construction. The mines are ahout fifty miles from here and of course all supplies of every sort have to he packed there.

No man should come to the Yukon country with less than $300 to $500 after paying all expenses to Forty Mile. Too much emphasis cannot he given to this warning. Credit for supplies is a thing of the past and cannot he expected again in this region.

BRITISH COLUMBIA.

TOO MUCH EXAGGERATION.—For several weeks past the provincial papers have heen puhlishing exaggerated accounts of the great gold finds ou Kaslo creek, says the Kootenai *Mail*. Such yarns will not only injure Kaslo, but the whole district. It is on a par with the exaggerated reports about the gold (placer and quartz) found in the Carihoo creek district, recently hlazoned to the world hy local contemporaries. The Kaslo correspondent of the Vancouver *World* thinks enough harm has heen done the town by this "besetting sin of western journalism," and calls a halt in the columns of that journal.

IDAHO.

Word from Silver City is to the effect that wonderfully rich ore bodies have heen encountered in the Tip Top mine. Assays from a streak fifteen inches wide, which extends to the 100-foot level and possihly farther, weut $500 in gold and 8,000 ounces of silver a ton. The lode is from thirty-five to forty feet wide. The Tip Top is owned by Colonel G. V. Bryau, formerly of Hailey, and G. W. Venahle of New York, who also owns the Red Elephant.

NEVADA.

Eureka District.

RICHMOND CON. MINING CO.—At the annual meeting in London receutly the chairmau stated that the output for the year ending February 28th last was 674 ozs. of gold, 27,389 ozs. of silver and 250 tons of lead. The mine has been worked for most part hy tributers and a considerahle quantity of ore taken out, but none of the rich pockets fouud which had distinguished the miue in the past. The ore has heen shipped and sold to the smelters at Salt Lake. The chairman advised against any further expeuditure in the effort to find new mines and helieves that more could he done by continuing to explore the Richmond mine itself. The balance of revenue on hand was sufficient to pay a dividend of 1s per share. The statement of the chairman and the report were approved hy the stockholders.

Washoe District.

ON THE COMSTOCK.—The official report of the work done in the Cousolidated California and Virginia mine last week is as follows: 1650-foot level—We have continued to stope ore from the new ore body, ahove and below the sill floor of this level, from the sixth floor up to the eleventh floor and on the eleventh floor have opened out two more sets of timhers to the south in good ore, making ten sets in all from north to south. From the south face on the eleventh floor, in the southwest corner, we have opeued out three sets of timbers upward. The twelfth floor carries five feet of good ore lying against the west or footwall, and the south face on this floor is in ore of good quality. 1700-foot level—In working upward from the sill floor of this level and outward to the north and south we have continued to extract good ore. 1750-foot level—From the sill floor of this level on the uorth side of the winze sunk from the 1700-foot level, our stoping in the ore hody has heen carried up to the fifth floor, and from the second to the fifth floor we have extracted 130 tons of ore assaying on the average $24.74 per ton. From all of these openings we have extracted duriug the week 300 tons of ore, the average value of which per mine car samples was $54.47 per ton. Shipped to the Morgan mill 340 tons and 860 pounds of ore, the average value of which per railroad car samples was $50.85 per ton. The average assay value per hattery samples of all the ore worked at that mill during the week—175 tons—was $49.67 per ton.

In the Ophir mine in the 1465 level workings some ore giving low assays is still heing found. In the Central tunnel workings on the 250 level a winze is being sunk at a point 80 feet in from the mouth of the southeast drift. On the 29th it was down 7 feet, and 17 tons of ore assayiug $21.52 per tou had heen extracted from it during the week. Porphyry carrying fine lines of quartz is heing cut in the northwesterly workings 117 feet ahove the tunnel level. The usual work has heen doue in the Mexican, Union Con., Sierra Nevada and Andes miues without important changes in formation. The joint Best & Belcher and Gould & Curry incline winze helow the 200-foot level of those mines is down 70 feet, passing through hard porphyry and quartz. In the Hale & Norcross mine the streak of ore in the face of the north drift on the 975 level is still holding out, and is of good quality. During the week three carloads of ore assaying $50.33 per ton were extracted. The winze on the 450 level of the Chollar mine, 350 feet south of the north line, is down 42 feet; bottom in fair-grade ore. Are stoping ore from the north end between the 450 and 550 levels. During the past week we have shipped to the Nevada mill for reduction 249 tons and 100 pounds of ore, the average hattery assays of which were $31.25. In the Potosi mine the connection at the hottom of the south winze from the 450 level is completed, and are running south on a streak of fair-grade ore.

COMSTOCK BULLION OUTPUT.—*Enterprise:* Following is the report of the ore and hullion yield during the past year. The first three quarters of the year are given and an estimate of the last quarter:

Quarter Ended March 31.—Consolidated California & Virginia—Total ore yield, 683 tons and 1,390 pounds; gross hullion yield, $12,291-.20; cost of extraction, $13,617.67; cost of transportation and reduction, $4,102 17; total cost, $17 749 84.

Chollar—Total ore yield, 1,046 tons and 1,600 pounds; gross hullion yield, $16,410 01; cost of extraction, $11,992 68; cost of transportation and reduction, $6,280 80; total cost, $18,273 48.

Yellow Jacket—Total ore yield, 477 tons and 365 pounds; gross hullion yield, $7,572 23; cost of extraction, $13,348 39; cost of transportation, $480 37; cost of reduction, $2,386 82; total cost, $16,215 68.

Quarter Ended June 30.—Con. Cal. & Va.—Total ore yield, 675 tons; gross hullion yield, $24,330 58; cost of extraction, $18,546 68; transportation and reduction, $4,218 75; total cost, $52,765 43.

Hale & Norcross—Total ore yield, 749 tons and 760 pounds; gross hullion yield, $7,999 85; cost of extraction, $18,218 49; transportation and reduction, $4,596 28; total cost, $22,714 77.

Belcher—Total ore yield, 325 tons and 72 pounds; gross hullion yield, $5,519 25; cost of extraction, $14,459 57; cost of transportation, $325 72; cost of reduction, $1,628 60; total cost, $16,413 89.

Crown Point—Total ore yield, 1,054 tons and 830 pounds; gross hullion yield, $10,340 88; cost of extraction, $18,366 54; cost of transportation, $1,277 95; cost of reductiou, $2,108 83; total cost, $21,753 32.

Occidental—Total ore yield, 321 tons; gross hullion yield, $5,416; cost of extraction, $3,694; transportation and reduction, $1,926; total cost, $5,620.

Yellow Jacket —Total ore yield. 203 tons and 65 pounds; gross hullion yield, $2,745 67; cost of extraction, $15,062 15; cost of transportation, $203 06; cost of reduction, $1,015 32; total cost, $16,280 53.

Quarter Ended September 30.—Consolidated California & Virginia—Total ore yield, 5,325 tons and 470 pounds; gross hullion yield, $204,-590 29; cost of extraction, 59,866 45; cost of transportatiou and reduction, $33,282 71; total cost, $93,149 16. Net yield or value on which taxes are levied, $111,441 13; hullion tax, $5,572 05.

Crown Point—Total ore yield, 1,288 tons and 1390 pounds; gross hullion yield, $10,363 38; cost of extraction, $8,633 35; cost of transportation, $837 66; cost of reduction, $2,577 39; total cost, $12,048 41.

The yield for the last quarter ending December 31, will not he filed until February, therefore a correct statement of the yield for that quarter is not available. The report for the first three quarters of the current year show that a total of 12,149 tons of ore were produced, yielding hullion valued at $307,579. The total yield for the year, wheu all the returns are filed, will probably reach $500,000.

NEW MEXICO.

HANOVER.—*Enterprise:* The new smelting plant of the New Mexico and Arizona Smelting Co. is heing pushed toward completion as rapidly as possible. The hoilers and engines, smelting stacks and a large lot of other machinery is on the ground. The assay offices and other auxiliary huildings are completed, and most of the timbers are already framed for the main smelter huilding. The opening of this smelter means the employment of several hundred meu on claims that have lain idle for years. Many small copper properties will he opened up when the owners have an opportunity to sell their small hatches of ore close at home. The new smelting company is working several of the old Santa Rita properties and employing many miners. It is quite likely some steps will he taken ere long to re-open the deep mines of Santa Rita. The owner of the property, J. P. Whitney of Boston, was out last week to look the ground over, with a view of opening up the property.

OREGON.

THE TOWN OF SUMPTER.—At the old town of Sumpter, ten miles northwest of McEwen, the terminus of the S. V. R. R., Messrs. Ellis & Cupid are equipping their placer ground with an electric light plant, two giant hydraulics and a string of pipe 5,000 feet in length, hesides enlarging the capacity of the ditches furnishing water for the mines. They are also ereeting a new sawmill with a capacity of 20,000 feet per day, ten hours.

SOUTH DAKOTA.

Just now, says a Custer City dispatch, Keystone seems to be the coming gold camp of the west. People are flocking in from all directions, until every house in the town and stables and sheds are filled to overflowing. No such rush has heen witnessed in the hills since the palmy days of 1887. Many are compelled to sleep out under the trees. There is now thought to he ore enough in sight to insure an output of 2000 tons a day for the next twenty years. The average value of ores in all the mines is ahout $15 per ton. The gold helt of the Keystone is a mile in width hy four miles in leugth.

UTAH.

AS TO THE SMELTERS.—*Tribune:* Inquiry among the leading mine-owners and managers of Park City regarding the late action of the smelter comhine or trust and the present attitude of its members, develops the existence of a great deal of righteous indignation in the minds of our ore-producers against that avaricious monopoly.

The result of this effort of the smelter men to compel the miners to pay extortionate charges for the smelting of their ores is likely to prove disastrous to somebody. It seems strange that, at this time, when silver and lead are selling at the lowest price in the history of the country, when the margin of profit in the ores of the most of our miues is merely nominal, when to retain any margin whatever of profit the mines have been compelled to reduce wages to the lowest point compatihle with decent living and to reduce expenses in every direction possihle, that just now the smelters should attempt to raise the smelting charges and to increase their already handsome profits. It seems incredible that there can he any necessity for this advance in charges. The smelters are certainly not paying any higher wages, and general supplies should be cheaper than heretofore.

Do they expect the mines to run at a loss, or do they anticipate that the wages of the men who handle the pick and drill will be reduced even below the preseut standard? It is much more likely that the mines will shut down, that the honest miner will be thrown out of employment, and that hitter suffering will be the portion of his wife and children.

Take, for instance, the great Anchor mine, with its immense hodies of low-grade ore, and whose ore at the present time pays a profit of less than $3 per ton even at the low rate of wages paid in that property. Is it reasonable to presume that this property can continue to operate under an increased charge of $2 per ton for the smeltiug of its ore? Are not the smelters pursuing the policy of "killing the goose that lays the golden egg?"

Already several informal meetings of the local mining magnates have been quite thoroughly discussed, and the consensus of oponion is that a convention of the ore-producers of the Territory should he called at once for the purpose of considering ways and means hy which the miners can be emancipated from the fetters that are being forged on their hauds hy the great smelter combination.

The mine-owners of Park City stand ready to unite with the other ore-producers of the Territory, or of the whole intermountain country, and put up money, if necessary, to huild smelters in Salt Lake valley or elsewhere to smelt their own ore and extricate themselves once and for all from the clutches of the smelter trust.

Should the opinion prevail that it would he hetter to close all the mines indefinitely, they will, if they do not close their own mines, guarantee not to submit to the rule of the smelter trust. In fact on this last proposition they seem determined, in any event, to refuse to make any contracts dictated hy the smelter combination.

THE SMELTERS' STATEMENT.—The smelting men in Salt Lake still emphatically deny that there is any combine hetween them as to smelting charges or prices of ore. They explain that their hids are based upon their need; that is, if they are short on a certain class of ore, they will bid high to get it, and if they do not need it they will not make any especial exertion to secure it. The result will he that some ore-producers will receive more than last year and others will receive less, but the smelting men do not think the average will fall much if any, below that of the last year.

WYOMING.

J. C. Davis, one of the Senatorial aspirants, speaking of the outlook for the State, said: "I am more hopeful over the outlook in Wyoming than I have heen in several years. There is every indication that there will be a great deal of development work done in the State next season. I have just let a contract for $15,000 worth of work to he done on the Penn mine in the Seminoe country, in Carbon county. Colorado parties have made several handsome offers for this property, but the owners intend to develop it themselves. The Four Mile placer claims are attracting much attention, and there is a hig demand for the ore from the iron mines near Rawlins. It is the finest fluxing ore that the Denver smelters can secure. There is no reason why 75,000 tons of it cannot be utilized for this purpose every year. The Union Pacific Company has completed a survey of a spur to the mines. It can be huilt for $10,000."

Coast Industrial Notes.

—Expert Moore figures that the Santa Fe system must expend $4,000,000 withiu the next five years to keep up its road aud rolling stock. Of this amount the A. & P. will have to expend $2,380,000—$1,706,200 for new rails.

—California has 333,310 milch cows, and each will average 3750 pounds of milk or 150 pounds of butter per year. The produce of 106,666 cows is consumed as milk; that of 19,200 into cheese, and that of 207,444 is made into hutter.

—The Mexican Northern railroad is to he extended from Sierra Mojada to the rich mining camp of Carmen on the Rio Grande horder, and thence across Presidio county, Tex., to Marathon, where connection will be made with the Southeru Pacific.

—The San Diego, Pacific and Eastern Railroad Company has incorporated. Capital stock $1,000,000. The object of the incorporation is to huild a railroad from San Diego northeasterly through El Cajon valley and to San Felipe pass, with a diverting road also from El Cajon valley via Poway to Escondido.

—The long-talked-of electric railroad hetween Los Angeles aud Santa Monica is rapidly approaching materialization. The plan is the utilization of the old Los Angeles and Pacific Railroad hy a corporation, which is understood to he practically the same as the Los Angeles Consolidated Company. A contract of sale has heen signed hy the owners of the old Los Angeles and Pacific wherehy, on certain terms, they transfer all the property to Mr. Stevens of this city, who is operating in hehalf of the Los Angeles and Pasadena Elec-

trie Railway Company, which is part of the Consolidated, the object being to make a continuous line through Los Angeles from the mountains to the sea.

—Capital has been secured for carrying out the plans for car works, blast furnace and steel works at Salmon bay, Puget Sound. D. H. Gilman of Seattle is at the head of the enterprise. It will require $3,000,000 of capital and give employment to 3000 men. It is proposed to secure motive power by generating electricity at Snoqualmie Falls, and a company already has been organized for this purpose.

—There are two values in flax—fiber and the seed. Our Northwest Pacific States are the best flax-growing district in the world. Many years ago the fiber was extolled by exports who saw it. But we were distant from market and did not press this branch of industry. Conditions are changing now, and the products of flax, fiber and seed or oil, will now or soon bear transport. This is one of the industries to be studied in these States.

—The Monterey & Fresno Railroad is designed to afford direct railroad transportation from Fresno to Monterey. Preliminary surveys have been made for the entire line—171 miles—and the permanent location of the greater part of the route has been completed. In July last, forty-six miles, from Monterey bay east, were put under contract and work on this division is progressing, with nine miles now graded ready for the track. The line will pass through Salinas, San Juan, Hollister, Firebaugh and Madera. It is expected to push work vigorously during 1895.

—The biennial report of the State Board of Fish Commissioners for 1893-4 states that California ranks sixth in the Union, with products valued at $3,044,310 with an annual appropriation of $8750, while Massachusetts ranks first, with an appropriation of $15,700 per annum. It has been stated that Eastern States required greater appropriations in this direction on account of greater population, but the report says the reverse is true, as the expense of protection is almost nothing in densely populated regions. The Commission recommends the appointment of a game warden in each county.

—The Columbian Colonization Company is incorporated by J. W. Wilson, H. P. Sweet and J. G. Foster to irrigate and colonize a tract of government land in San Bernardino county, on the Atlantic & Pacific and the Southern California Railroads, and on branches of the Santa Fe system. At the upper narrows at Victor on the Southern California Railway, the river flows through a gorge 300 feet deep and 150 feet wide. By building a dam 150 feet high at this point the company propose to obtain a water supply sufficient to irrigate 340,000 acres of desert land. It is their intention to lay out a city to be called Columbia, with water power for electric plants, a beet-sugar factory, canaigre works, a creamery and a cold-storage warehouse. The capital stock is $4,000,000.

—It is stated at Union Pacific headquarters that for some time past it has been the ambition of Receiver McNeill of the O. R. & N. Co. to bring about a separate receivership for the Oregon Short Line and Utah Northern with the Oregon Navigation Company, thereby making the two roads an independent system. But the scheme was not to end there. A California line was to be secured by extending the branch a distance of 400 miles, connecting the O. R. & N. Co., thus giving the company a through line from Huntington to the coast via Portland. For months this has been the dream of Major McNeill, but when he broached the subject of independent line to Mr. Boissevan, who has large interests in both properties, it is understood that gentleman told the Navigation Company's receiver he was entirely satisfied to have the management in the control of the Union Pacific.

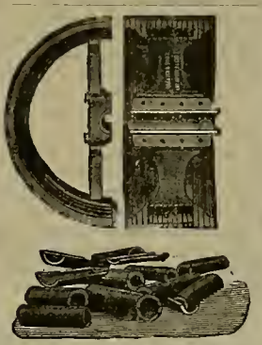
—A conservative epitome of California productions in '94 show that California mines yielded $18,000,000 in the preceding twelve months, of which over $12,000,000 was gold; the value of the salt product in 1894 was $120,000; borax product, 1894, $860,000; mineral waters, $300,000; natural gas, $90,000; petroleum and bitumen products, $1,250,000; quicksilver, 26,400 flasks; value of San Francisco manufactures in 1894, $83,310,000; beet sugar produced, 35,000,000 pounds; wheat crop, 22,414,900 bushels; brandy distilled from grapes, 1,300,000 gallons; California canned fruit, 1,240,000 cases; barley crop, 5,060,000 bushels; bean crop, 72,000,000 pounds; raisin crop, 54,600,000 pounds; dried fruit product, 125,000,000 pounds; prune crop, 32,500,000 pounds; wool product, 26,000,000 pounds; hop product, 40,000 bales; orange crop, 10,000 carloads; butter, 50,000,000 pounds; cheese, 15,000,000 pounds.

Krogh M'f'g Co.,
MANUFACTURERS OF
Mining Pumps, Pan Staves, Leaching Tanks and also the famous

Krogh Mining Hoist!
The best and cheapest on the market, and for strength and durability unsurpassed.
Send for Catalogue. 51 Beale St., San Francisco.

OUR PIPE IS FOR SALE.

For Hydraulic Mining and Irrigation Purposes Our Sheet Iron and Sheet Steel Riveted Water Pipe Is Unexcelled.
We Have Also a Large Line of the MATHESON JOINT (Lap-Welded) Pipe, for Which We Are Agents.
Our Prices Are Low; Our Pipe Is Superior, and We Want More Business. May We Quote You Prices?
PIPE FITTINGS, TOO.
RISDON IRON WORKS,
SAN FRANCISCO, CAL.



EVERY PULLEY GUARANTEED
FOR DOUBLE LEATHER BELT.
Dodge Independence Wood Split Pulley
Is the lightest, strongest and most convenient Pulley made.
SIMONDS SAWS
AND MACHINE KNIVES.
RUBBER BELTING,
RUBBER HOSE, COTTON HOSE, PACKING.
LEATHER BELTING,
DODGE WOOD SPLIT PULLEYS,
EMERY WHEELS, FILES.
GRAPHITE AND GRAPHITE GREASE,

L. C. MARSHUTZ. T. G. CANTRELL.
NATIONAL
IRON WORKS,
N. W. Cor. Main & Howard Sts., San Francisco.
MANUFACTURERS OF
STATIONARY AND COMPOUND
ENGINES,
FLOUR, SUGAR, SAW AND QUARTZ MILL
MACHINERY.
AMALGAMATING MACHINES.
CASTINGS AND FORGINGS
OF EVERY DESCRIPTION.
All work tested and guaranteed.
IMPROVED PORTABLE HOISTING ENGINES.
Sole Manufacturers of
Kendall's Patent Quartz Mills.
Having renewed our contract on more advantageous terms with Mr. S. Kendall for the manufacture of his Patent Quartz Mill, we are enabled to offer these mills at Greatly Reduced Prices. Having made and sold these mills for the past 14 years, we know their merits, and know that they have given perfect satisfaction to purchasers, as numbers of commendatory testimonials prove. We feel confident, therefore, that at the prices we are now prepared to offer them, there is placed within the reach of all a light, cheap and durable mill that will do all that is claimed for it and give entire satisfaction.
MARSHUTZ & CANTRELL.

FRANCIS SMITH & CO.,
—MANUFACTURERS OF—
SHEET IRON & STEEL PIPE
FOR TOWN WATER WORKS.
Hydraulic, Irrigation and Power Plants, Well Pipe, Etc., all sizes.
130 BEALE STREET, SAN FRANCISCO, CAL.
Iron cut, punched and formed, for making pipe on ground where required. All kinds of Tools supplied for making Pipe. Estimates given when required. Are prepared for coating all sizes of Pipes with a composition of Coal Tar and Asphaltum.

Adamantine Shoes and Dies
—AND—
CHROME CAST STEEL
Cams, Tappets, Bosses, Roll Shells and Crusher Plates.
These castings are extensively used in all the mining States and Territories of North and South America. Guaranteed to prove better and cheaper than any others. Orders solicited subject to the above conditions. When ordering, send sketch with exact dimensions. Send for Illustrated Circular.
Manufactured by CHROME STEEL WORKS, Brooklyn, N. Y.
H. D. MORRIS, Agent, 220 Fremont St., San Francisco.
Special attention given to the purchase of Mine and Mill Supplies.

Stamp Cam.

NEW METHODS. STORAGE BATTERIES. NEW RESULTS.
THE HOUGH STORAGE BATTERY opens a new era in electrical development. We are now prepared to fill orders for complete plants for lighting or power. Residence lighting now an economical success. Stores, warehouses, mines, mills or street railways at reduced prices. Estimates furnished. Correspondence solicited.

Electrical Progress.

Direct Conversion of Light Into Electricity.

At the last meeting of the Societe Iuternationale des Electricians, M. Ch. Marechal showed experimentally, hy means of an electro-chemical actinometer, that luminous energy is transformed into electrical euergy mechanically—availahle even at long distances—not through the calorific or chemical power of the light, but hy virtue of a third force, which the writer calls actiuic foree.

This transformation is effected in all the divisions of the spectrum, but depends on the coloring matter employed for sensitizing the plates of the actinometer, the sensitivcuess of which is so great that the light of the candle at a distance of some meters produces effects that are as clear as they are instantaneous.

After diseussing certain applications to telegraphy and photography, M. Marechal in an hypothesis which, though bold, is based on facts ascertained by ohservation and experience, shows once more the close connection hetween electrical and luminous phenomena; then he showed the intimate relations existing hetween solar light and the great natural phenomena, such as terrestrial magnetism, the different variations of the magnetic needle, the aurora horcalis, earth currents, etc.

This would seem to mark the beginning of a new epoch in optical physics and to open new avenues of investigation which may lead to the most important results. While this hrief notice, which is all we have at present, suggests nothing incompatible with our present heliefs or the teachiugs of Maxwell, it seems likely to give those teachings a new significance and to give them a eoncrete value that they have not heretofore possessed.

France Encourages Electrical Progress.

Frauce has for somc time past bceu specially active in the application of electric power to cauals, a fact due probably to the importanee aud extent of her canal system. The latest sucessful trial reported is one on the canal hoats of the Havre-Paris-Lyons compaignie, in which a trausferahle electric motor and rudder combination is used, while the motor has been driven hy current from storage hatteries. The caual boat, haviug a length of thirty-eight meters and carrying 180 tons, is driven at a speed of eighty-five centimeters per second, an iucrease of forty per cent over the speed with two horses, while the electrical energy consumed was about four aud six-tenths horse power. At times a speed of one meter (three feet three inches) per second was obtained. It is now proposed to employ also a trolley system, as on the Bourgogue canal, and to let the feed water that maintains the levels at the proper height operate dynamos generating the necessary current. France has always heen foremost in the application of electricity to navigation.

A COMMON EXPERIENCE among those who have to do with electrical machinery is the paralyzing effect which the electric curreut exerts upon an ordinary watch. The mechanism of most watches being of hard steel, highly polished, renders them peculiarly sensitive to magnetic influence, and consequently unreliahle as timekeepers. Formerly non-magnetizahle watches were regarded as little more than a uovelty; now, however, the rapid spread of electricity in its multifarious forms has made them a necessity.

DR. WELLINGTON ADAMS, president of the Chicago and St. Louis electric road, says the road " will most certainly he huilt, hut not uutil after a revival in business. Already $8,000,000 of the $10,000,000 worth of honds have been placed, and it will not he much trouble to place the remainder. The grading and securing of right of way is going steadily on."

An Explosion in an Iron Foundry.

The explosive power of water when suddenly converted into steam may not be thoroughly understood or even fully comprehended by some mechanics, and an explosion that wrecked a foundry was caused by a lack of just such knowledge on the part of the foundrymen. Pouring off is always done at the end of the day, and sometimes it is late at night before the bottom is dropped and the furnaceman at liherty to go home. Under such conditions it is not strange that a man would do all that he could to hurry up things, that he might get away early.

It is the custom, in most foundries, to throw several pails of water on the pile of slag and cinder that comes down, red hot, upon the sand which has been placed under the cupola to receive that which falls when the hottom is dropped. A shallow cavity is hollowed out of the sand to receive the slag, and several pails of water, or a stream from the hose, deadens the intense heat radiated from the pile of glowing matter. It is supposed that the cupola man, in order to get away sooner, hit upon the expedient of getting the water ready beforehand, so he would have less to do after the bottom came down. Accordingly, the hole scooped in the sand underneath the cupola was half filled with water, and at a given signal the prop was pulled away and the bottom came down. Then the explosion occurred, wrecking the building, killiug and wounding several workmen and setting the wreck on fire. It was caused by the water hecoming suddenly expanded into a gas, which occupied many times the space filled hy water.

We can throw a pail of water into a cupola charged with molten iron, and no explosion will occur which can amount to much. But confine that water in a pipe and plunge the pipe into melted irou and there will be the livelicst kind of an explosion as soon as the heat gets well at the euclosed water. It is this thing which sometimes causes the disastrous explosions in cupolas, when pistons and other apparently harmless pieces of iron explode with terrihle force and damage.—Scientific Machinist.

Machinery of a Cruiser.

The extent and power of machinery construction are wonderfully exhihited in the working equipments of the latest Government cruiser. There are 61 separate engines, not counting cylinders, which would run up to 120, for main, auxiliary and pumping purposes. The low-pressure piston is 92 inches in diameter, and an area of 46 square feet and an initial load of 100 tons. The condenser tubes, if placed end to end, would form a tuhe 33 miles long, and the cooling water passed through these tubes equals 36,000,000 gallons per day, or enough to supply a large city with water. The main boilers, if placed end to end, would form a tunnel 156 feet long and large enough for a train of cars to pass through. The heating surface is equal to 1½ acres.

Armor Plate for Russia.

The Bethlehem, Pennsylvania, Iron Compauy has the whole contract for supplying armor for Russia's two new battle ships, the Sebastopol aud Petropalovak. The contract calls for something over 12,000 tons of armor plate to fit up the two ships. It amounts to about $4,000,000. The American company secured the contract over fourteen eompetitors, comprising the armor plate manufacturers in the United States, England, France, Italy and Germauy. The contract is regarded the largest ever awarded in Europe.

THE JONES ROCK DRILL

IS THE

Only Successful Hand Power Drilling Machine Ever Invented.

It is strong, durable, reliable, simple, compact, light, easily handled and operated by one man, and will reduce the cost of rock drilling at least Fifty per cent.

Our handsomely illustrated pocket catalogue fully explains the features and workings of the drill. It should be in the hands of every mine owner, leaser, contractor and prospect or in the West. *Sent free on application.*

If you are interested in Rock Drilling Correspond with us.

WE CAN SAVE YOU MONEY.

FRANK T. SUTHERLAND, M'g'r Pacific Coast Agency.

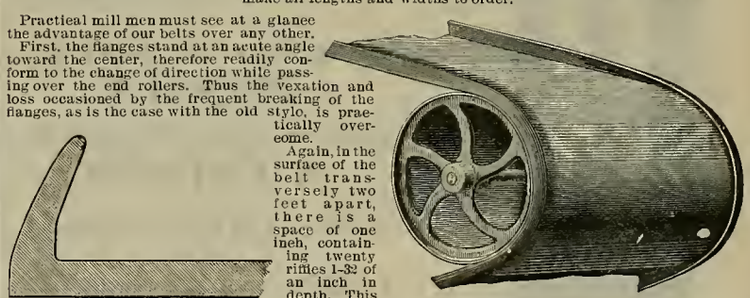
Blasdel Improved Concentrating Belt.

We keep in stock belts suitable for the Frue, Triumph, Johnston and Tulloch machines, and make all lengths and widths to order.



Practical mill men must see at a glance the advantage of our belts over any other.

First, the flanges stand at an acute angle toward the center, therefore readily conform to the change of direction while passing over the end rollers. Thus the vexation and loss occasioned by the frequent breaking of the flanges, as is the case with the old stylo, is practically overcome.

Again, in the surface of the belt transversely two feet apart, there is a space of one inch, containing twenty riffles 1-32 of an inch in depth. This tends to equalize the pulp and prevents it from banking on the edges, or forming channels. This riffle saves fine sulphurets and quicksilver that would escape with the tailings from a belt with an entirely smooth surface.

H. G. BLASDEL, JR., Manager,

(A CORPORATION.)

Constantly on hand a full assortment of Manila Rope, Sisal Rope, Duplex Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc. ☞Extra sizes and lengths made to order on short notice

611 and 613 FRONT ST., San Francisco, Cal.

Practical Information.

Wages of Steamship Building.

The following report shows the rate of wages paid by Clyde builders of ocean steamships and by steamship owners, and are printed in Consular Reports. The rates given are by the hour:

Description.	Wages. Pence.	
Engineers, general	6½	$0.13
Pattern makers	6¾	.13½
Machinists, in engineer shop	6	.12
Boiler makers	8	.16
Plumbers	8	.16
Pipe fitters	6¾	.13½
Shipwrights	7½	.15
Ship joiners	7¼	.14½
Drillers	8½	.17
Fitters-up	9¼	.18½
Riveters	10	.20
Calkers	9	.18
Painters	7½	.15
Furnace men	6	.12
Sheet-iron workers, general	6½	.13
Coppersmiths	7¾	.15½
Iron molders	7½	.15
Brass molders	8	.16
Blacksmiths	7½	.18
Laborers	5	.10
Frame setters	8½	.17

The hours of labor are fifty-four per week for about forty-eight weeks in the year. The ships are nearly all constructed of steel. Iron vessels are now as rarely built there as wooden ships. Several of the trades mentioned are employed by the piece. These include the riveters, platers, frame setters, fitters and calkers. The riveters work in squads, consisting of two riveters, a holder-on and a rivet boy, and they are paid at the rate of so much per hundred rivets put in. The larger the vessel the higher the rate, and special prices are paid for riveting keels and stringer plates. A steamer of over 5000 tons commands extra wages. On ordinary vessels good squads (two riveters, a holder-up and a rivet boy) will make at present about $6.68 per day, but the average for Government work is above this. The piece men are sometimes irregular in their employment, and, if overtime is excluded, do not work more than five days per week.

The shipwrights have a standard wage of fifteen cents per hour, but the joiners, blacksmiths and engineers have what is known as a sliding scale.

In the case of engineers the pay varies from twelve to thirteen and a half cents per hour, blacksmiths from twelve to sixteen cents per hour.

The Speed of Trolley Cars.

The speed of a trolley car when passing any given point has been a matter upon the determination of which a good deal of discussion has been expended. To put a revolution counter upon the axle would solve the problem, but it is frequently desirable to ascertain the speed of a car without the assistance of a street car company. Particularly is this desirable when seeking evidence that the cars are being run at a higher rate of speed than allowed by law. It is well known that the motor gives forth a peculiar sound when the car is running. This sound Whittier in his poem on "The Broomstick Train" likened to the purring of a witch's cat, and it is in this purring sound that the speed indication lies. Whenever a number of blows or taps are delivered in regular sequence, they will, if their frequency be great enough, form a musical note. The reason for this is, that the ear cannot rid itself of one sound before another reaches it; consequently when the number of notes rises above a certain number per second, a musical note is the result. The eye possesses a similar faculty called "persistence of vision," which makes the firebrand give an apparently continuous circle of fire when whirled swiftly about. About one-sixtieth of a second is said to be the limit of persistence of vision, and thirty sound vibrations per minute are probably the least number which the ear can recognize. The lowest note on a seven-octave piano has about thirty-three vibrations per second, and middle C about 246. It is the striking or meshing of the gear and pinion teeth which causes the "purring" of the street car motor, and if the tone caused by the meshing teeth has a pitch of "middle C," we know that 264 teeth are meshing per second. Then the number of teeth on gear being known, also the diameter of the car wheel, it is comparatively easy to calculate the speed of the car at the instant the sound observation was made, in spite of all efforts of the company to prevent the car speed from being known.—Cassier's Magazine.

Doesn't Pay to Pick Up Nails.

A very striking illustration of what the low cost of manufactures of iron and steel really means is furnished by a remark incidentally made by William Garrett, of Joliet, Ill., the famous inventor of the rod mill which bears his name. In a lecture at Joliet, says the *Iron Age*, he stated that "wire nails are sold so cheaply that it is estimated that if a carpenter drops a nail it is cheaper to let it lie than to consume the carpenter's time to lift and use it, and it is claimed by good authority that one keg out of five is never used but goes to waste." We have had the curiosity to do some figuring on the proposition made. Assuming that it takes a carpenter ten seconds to pick up a nail which he has dropped, and that his time is worth thirty cents an hour, the recovery of the nail would cost 0.083 cent. There are 200 six-penny nails in a pound, which is worth, at 90 cents base and 65-cent average per keg, 1.55 cents per pound. This would make the money value of the individual nail 0.0077 cent. Or in other words it would not pay to pick up ten nails, if it took ten seconds of time worth thirty cents an hour to do it in.

William J. Chalmers Esqr.
Pres. Fraser & Chalmers.
Chicago. Ill.

Dear Sir:-

Your letter of July 7th. is duly received.

In regard to your enquiry regarding our Riedler Compressor, supplied by your Coy, over eight months ago, I must say, that the Compressor is giving excellent results, and every satisfaction, while running either by steam, or water power.

During the last twelve years, I have seen operated, and have operated, many different makes of air Compressors, including the Eclipse, Reliance, Burleigh, National, Rix, & Firth, Ingersoll Sargent, etc. etc. and in no instance, have any of the above given the results of the Riedler. Therefore, I have no hesitation in saying that the Riedler, is the best, and most economical Compressor on the market today. We have made comparitive tests here, of the Ingersol Sargent, and Riedler, which show, greatly in favour of the Riedler.

Yours very truly,

Robt. Duncan Jr.

Market Reports.

The Markets.

SAN FRANCISCO, Jan. 3, 1895.

The eclipse of '94 still surrounds lead and silver, "sixty and three" heing the continued quotation. Neither the proposed Japan loan nor Congressional action or inaction seem to affect the morihund market. Kansas City and New York men have this week shipped large quantities of har silver to the City of Mexico, to he coined at the Government mints into Mexican silver dollars. Transportation and mintage charges amount to nearly seven per cent. A member of the shipping firms says: "The Mexican silver dollar is at a premium of ahout seven per cent and foreign exchange in Mexico is at a discount of about seven per cent, a condition the reverse of that which now prevails in the United States. This is illustrative of the fact that countries on a silver hasis are prospering on the low price of silver, while gold-hasis countries are suffering."

A circular issued hy the freight department of the Southern Pacific to its agents states that, until further advices, the rate of exchange hetween Mexican and American money will he $2.02. Fractions of five-tenths or over will he considered one cent, and fractions of less than five-tenths will he dropped.

New York Prices.

NEW YORK, Jan. 3.—Following are the closing prices for the week:

	Silver in London.	Silver in N. Y.	Copper.	Lead.

How the mysterious principle of life fights to maintain the heat of a body, and then finally surrenders, is curiously illustrated by Pictet, the Genevese chemist. A dog placed in a copper receiver, kept at from 75° to 130° below zero Fahr., became warmer than when he was put in by half a degree during the first ten minutes; and after an hour and a half he was only one degree colder. But soon afterward the animal suddenly died.

A WORLD'S FAIR will be held in Amsterdam this year, opening on May 1st and closing on November 1st. Montreal proposes to hold one in 1896, Baltimore in 1897 and Paris soon afterward.

Mining Share Market.

SAN FRANCISCO, Jan. 3, 1895.

The regular holiday demoralization, added to an apathetic market, made a depressing total for the old year. '95 opens hetter, there heing a noticeable improvement in value and volume. Work has heen resumed in the Seg. Belcher, Kentuck, Crown Point and Yellow Jacket. Crown Point is shipping ore to the Mexican mill, and the Con. Cal. and Va. to the Morgan mill. During the last month of '94, local mining incorporations disbursed $114,000 in dividends.

The following illustrates the changes of the week:

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

CAN-TESTING MACHINE.—Joseph Black, San Francisco, Cal. No. 531,616. Dated Dec. 25, 1894. This invention consists of a vertically rotating wheel, the lower periphery of which dips into a tank of water. Above the top of the wheel is a mechanism by which cans are delivered, so that as the wheel rotates a can will he received hetween clamps upon the periphery of the wheel, which press against the ends of the can. The end of the can having an opening, fits against the mechanism through which air is admitted under pressure into the can, and then if the can leaks in any way it will he shown hy hubbles escaping from it when it passes into the water tank. Two chutes are arranged near the tank, so that as the caus rise out of the water those which are perfect are delivered into one of the chutes, and those which show signs of leakage are delivered into the other to he repaired. The mechanism operates automatically, with the exception of the discharge of the defective cans, which may he effected hy the movement of a lever hy an operator.

TELLURIAN.—Cornelius G. Sullivan, Woodland, Cal. No. 531,399. Datod Dec. 25, 1894. The object of this invention is to provide a simple and inexpensive instrument for illustratiug the movement of the earth and moon ahout tho sun, the movement of the moon about the earth, solar and lunar eclipses, and, finally, to illustrate the cause of the tides in connection with what may he termed the "centrifugal theory." The tellurian consists of a primary hody; a suspeuding line, acting hy torsion to rotate said hody; a secondary body, and a connection between said secondary body and the primary body, whereby the former is caused to revolve ahout the latter by the rotation of said primary body. In the simplest form of the device the two bodies may he mere halls, the larger or primary body, representing the sun, being suspended hy means of a twisting string. A wire hracket connected with this larger hall suspends, hy means of another twisting string, a smaller or secondary hall representing the earth, and from this hall is supported, hy means of a wire arm, a satellite hody or hall representing the moon. The operator has only to hold or otherwise suspend the device from the main line, having first properly twisted hoth the suspending strings, and the proper motions are imparted hy tho torsion of said strings. These means for giving the movements simplify the instrument and make it possihle to economically construct it and supply it to all schools.

GLOVE.—Reuhen Raymond, San Francisco, Cal. No. 531,386. Dated Dec. 25, 1894. The main object in this glove is to avoid any seam in the crease or line of the ball of the thumb, thus making it seamless. Another object is to conform the thumh of the glove to the natural position of the thumb of the hand, hoth in front and back. The glove is constructed of a main portion fashioned to form the front, one side and the index and small fingers of the body of the glove, said portion having formed integral with the palm thereof the front of the thumh; a piece secured along one edge in the hack of the main portion of the glove, and which forms the hack of the second and third fingers; fourchettes forming the front and sides of said fingers, and an independent piece which forms the hack of the thumh, said piece having a point wbich is stitched to the hase of the hack of the index finger and to the adjoining side of the hack piece.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING DECEMBER 25, 1894.

531,495.—CARTRIDGE CRIMPER—T. R. Barney, S. F.
531,616.—CAN-TESTING MACHINE—Jos. Black, S. F.
531,588.—BRAKE—Dickinson & Warner, Tacoma, Wash.
531,372.—SHOULDER BRACE—W. M. Gamble, New Whatcom, Wash.
531,535.—HARVESTER—G. W. Ingersoll, Stocktou, Cal.
531,378.—GATE—J. E. Knapp, Brownsville, Ogn.
531,386.—GLOVE—R. Raymond, S. F.
531,571.—ANIMAL TRAP—V. J. Scherh, Pasadena, Cal.
531,399.—TELLURIAN—C. G. Sullivan, Woodland, Cal.
531,451.—CAN-HEAD DIE—N. Trayer, Astoria, Ogn.
531,580.—CINCH PLATE—A. P. Weeks, Santa Cruz, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible by mail or telegraphic order). American and Foreign patents obtained, and general patent husiness for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Every Inventor Wants a Good Patent

Or none at all. To secure the hest patents Inventors have only to address DEWEY & Co., Pioneer Patent Agents, No. 220 Market St., San Francisco.

There are many good reasons why Pacific Coast Inventors should patronize this Home Agency.

It is the ahlest, largest, hest, most convenient, economical and speedy for all Pacific Coast patrons.

It is the oldest on this side of the American continent, most experienced, and in every way reliahle.

Conducted from 1863 by its present owners (A. T. Dewey, W. B. Ewer and Geo. H. Strong), this agency has the best knowledge of patents already issued and of the state of the arts in all lines of inventions most common on this coast.

Patents secured in the United States, Canada, Mexico, all British colonies and provinces, England and other civilized countries throughout the glohe.

Caveats filed, assignments duly prepared, examinations made, and a general Patent Agency business conducted.

Established and successfully and popularly conducted for nearly thirty years, our patrons number many thousands, to whom we refer with confidence, as men of influence and reliahility. Old and new inventors are cordially offered the complimentary use of our library and free advice, etc. No other agency can afford Pacific States inventors half the advantages possessed by this old, well-tried and experienced firm.

BACK FILES of the MINING AND SCIENTIFIC PRESS (unbound) can he had for $3 per volume of six months. Per year (two volumes), $5. Inserted in Dewey's patent binder, 50 cents additional per volume.

THE CALIFORNIA DEBRIS COMMISSION having received applications to mine by the hydraulic process from Mello & Costa, in the Spring Valley mine, near Cherokee, Butte Co., to deposit tailings on flat ground; from H. E. Picket, in the Kentucky Flat mine, near Georgetown, El Dorado Co., to deposit tailings behind a dam in North Otter creek; from Wm. Johnson, in his mine near Volcano, Amador Co., to deposit tailings behind a dam in Clapboard gulch; from El Dorado Water and Deep Gravel Mining Co., in the Henrietta mine, near Placerville, El Dorado Co., to deposit tailings behind a dam in a dry ravine; from Leroy Hedge, in his mine near Brownsville, Yuba Co., to deposit tailings behind a dam in a ravine; from Rolland & Vanderburg, in the Epley mine, near Placerville, El Dorado Co., to deposit tailings behind a dam in a ravine; from the York Mining Co., in its mine near Brownsville, Yuba Co., to deposit tailings behind a dam in a ravine; from Hancock & Daly, in the Last Chance mine, near Placerville, El Dorado Co., to deposit tailings behind a dam in a ravine; from Goodman Bros. and Goodman & Bund, in their mines near Volcano, Amador Co., to deposit tailings behind a dam in Ashland creek; from Hadley & Bolles, in the 49 Flat mine, near Volcano, Amador Co., to impound tailings behind a dam in 49 gulch; and from G. A. Melnecke et al., in the Fine Gold mine, near Vallecita, Calaveras Co., to impound tailings behind dams in a dry ravine, gives notice that a meeting will be held at Room No. 92, Flood Building, San Francisco, Cal., on Jan. 14, 1895, at 1:30 P. M.

—♦THE♦—

Ore Deposits of the United States.

By J. F. KEMP, A. B., E. M., Professor of Geology School of Mines, Columbia College.

Second Edition, Revised and Enlarged, New Illustrations.

A practical review of the ore deposits of this country. A valuable additiou to up-to-date mining literature, of value to the Pacific coast. Sent postpaid upon receipt of price, $4.00. Address

Mining and Scientific Press,
220 Market Street, San Francisco. Cal.

DIVIDEND NOTICE.

THE GERMAN SAVINGS AND LOAN SOCIETY

526 California Street.

For the half year ending Decemher 31, 1894, a dividend has been declared at the rate of five (5) per cent per annum on Term Deposits, and four and one-sixth (4 1-6) per cent per annum on Ordinary Deposits, payahle on and after WEDNESDAY, January 2, 1895.

GEO. TOURNY, Secretary.

Books on Working Ores.

BY GUIDO KUSTEL. M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals Without Quicksilver. By GUIDO KUSTEL M. E.

This rare book on the treatment of gold and silver ore without quicksilver is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, $3, postpaid. For sals by THE DEWEY PUBLISHING CO., 220 Market St., San Francisc.

BY C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant; 164 pages, octavo. Illustrated by twelve lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, $3. Sold by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

Practical Treatise on Hydraulic Mining.

BY AUG. J. BOWIE, JR.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on heavy grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdys, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc. A very practical work for gold miners and users of water. Price, $5, postpaid For sale by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

INVENTORS, Take Notice!

L. PETERSON, MODEL MAKER,

226 MARKET ST., N. E. Corner Front (Up Stairs), SAN FRANCISCO. Experimental machinery and all kinds of models. Tin and brasswork. All communications *strictly confidential*.

20-Stamp Mill for Sale.

In Southern California, a 20-stamp Gold Quartz Mill, with engine, hoiler, self-feeders, rock-breaker, etc.

As the premises are adjacent to Railroad, the Mill could he conveniently removed. Can he had at low price for cash. Address: "Quartz Mill," care MINING AND SCIENTIFIC PRESS, San Francisco.

The McGlew Ore Concentrator Company.

PATENTED SEPTEMBER 19, 1893. CHEAPEST, SIMPLEST, MOST DURABLE AND CLOSEST SAVING CONCENTRATOR IN USE. FRANK BARRERE, Secretary and Manager.

Can be seen in operation at the Company's works, 132 Main Street, San Francisco.

Office, 116 Davis Street.

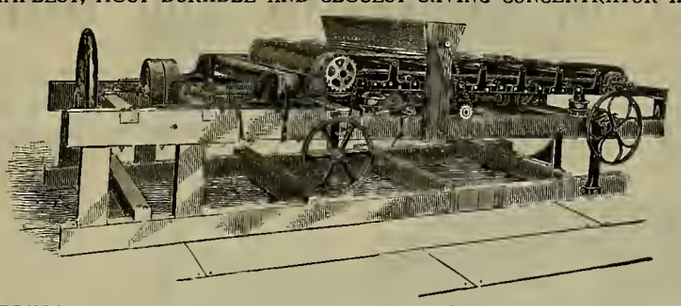
NINETY-FOUR AND ONE-HALF PER CENT
—SAVED—
ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness, combining both Side and End Motion with a Bumping Belt.

SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILST IN OPERATION.

CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE.....$350 EACH
Including prepared canvas belt 4 ft. 6 ins. wide.



FALLS MINE, Igo, Shasta Co., Cal., May 25th, 1893.

THE McGLEW CONCENTRATOR COMPANY:—I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years' experience with different concentrators, I believed them to be the best.

Now, after a thorough trial of the McGlew Ore Concentrator, on ores difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ores. It is doing CLEANER and CLOSER work than I had believed possible for any concentrator to accomplish.

Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 94½ per cent; from East ledge, * * * a saving of 92 per cent. The concentrator runs very easy and requires but slight attention. One man attends to rock breaker, crusher and concentrator.

You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily recommend it to the mining public. Yours respectfully,
E. L. BALLOU, Propr. Ballou Reduction Works.

GLADSTONE MINING COMPANY,
C. J. Clark, M. E., Gen'l, Supt.
FRENCH GULCH, Shasta Co., Cal.,
Dec. 12, 1891.

MESSRS. ADAMS & CARTER, San Francisco, Cal.—DEAR SIRS: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the FRUE in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for TWELVE MONTHS. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to to mention. In order to give an idea of the work they are doing here, I will state that the ore has varied monthly from $5 to $[illegible] per ton and the tailings from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six-foot Frue Vanner too highly, and it is the only table that I will have in my mill.
C. J. CLARK, Gen'l Supt.

MANUFACTURERS OF

Johnston's Concentrator, Bryan Mills,
Challenge Ore Feeders, Air Compressors,

MINING, MILLING, PUMPING and HOISTING PLANTS.

THE WOODBURY ORE CONCENTRATOR WITH IMPROVED BELTS was awarded the Highest (Bronze Medal) Premium at Mechanics' Institute, 1890 and 1891 MORE THAN DOUBLE THIS CAPACITY with one-half less power and occupying less than one-half the space of any other concentrator. Built of best Steel and Wrought Iron. Strong and durable. Price $575 f. o. b. Send for Catalogue and Testimonials.

The annexed cut shows the belt in its improved form, which consists of corrugated edges, to form an expanding top edge. THE IMPROVED MACHINE HAS THE FOLLOWING MERITS: First—The improved belts, which consist of seven, are constructed and arranged so as to allow each belt to receive a portion of the pulp in such a manner as to relieve the machine of its load, thereby giving it twice the capacity of other concentrators, and enabling it to work from 12 to 15 tons of ore per day. Second—The machine equalizes the load by several compartments, thereby working more regularly and with much less attention than is necessary to give other concentrators using wide belts. Each of the belts on this machine takes care of the pulp that is allowed to it—in this way preventing the pulp from running to the lower side of it, as is the case when a machine becomes out of level where wide belts are used. Third—The belts run on a perfect line, needing no adjustment to prevent their running from side to side, as in other concentrators. Fourth—The belt surfaces are improved by indentations and corrugations, causing the Concentrator to save fine sulphurets and quicksilver, and perform close work. Fifth—The belts have fluted or corrugated edges, to form an expanded top edge, which effectually prevents from cracking. Sixth—The feed arrangement is perfect. Seventh—The machine is constructed of iron, with steel crank-shaft self-oiling boxes, and everything made in the most thorough manner, enabling it to run with very little attention or wear.

Geo. E. Woodbury,
Manufacturer,
141 to 143
First St.,

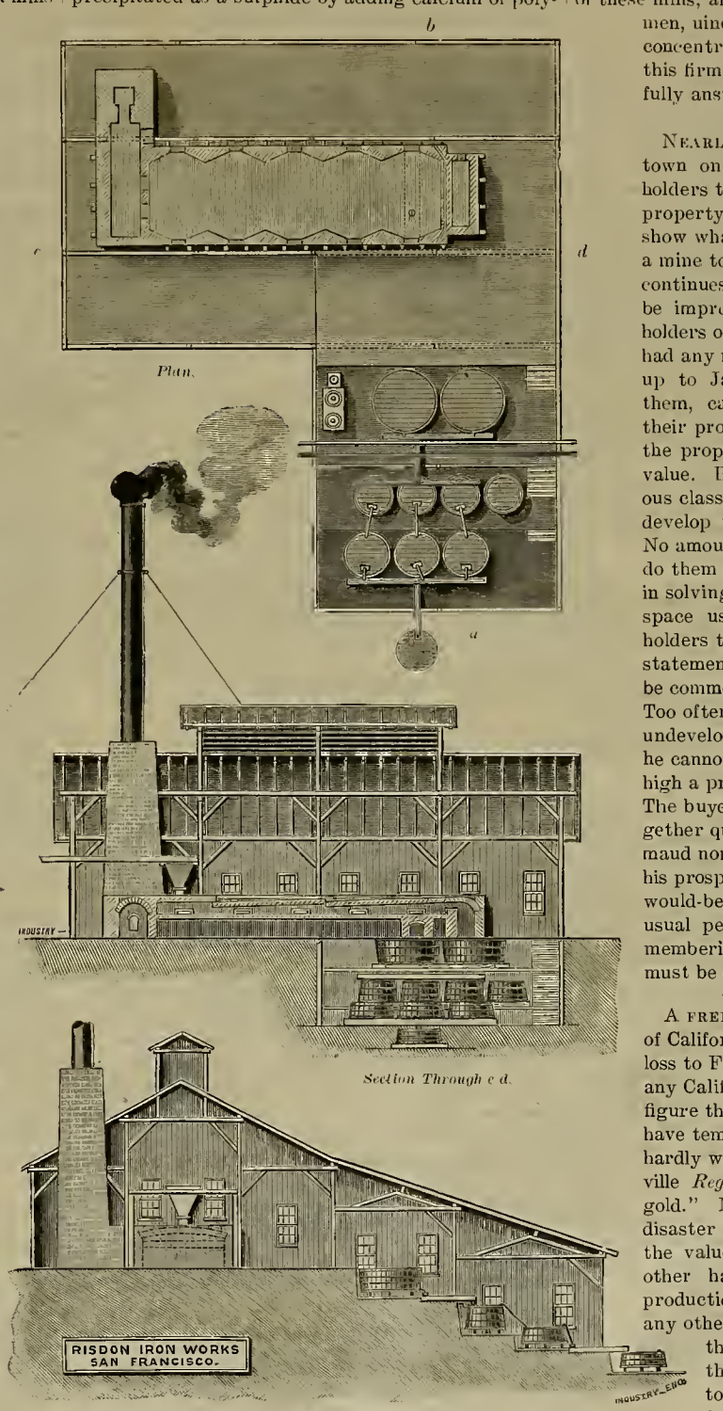
Chlorination Mill.

We illustrate this week one of the improved mills for working concentrates. It will be noticed that the roasting is done in a reverberatory furnace, as this style has proven the most satisfactory. We give a description of the mill and the process, as described by the manufacturers:

When concentrators or vanners are used in gold mills, their product is known as "concentrates" or "sulphurets." These contain the residue of the precious metals that has escaped amalgamation in the battery and on the "plates." The value of a ton of these concentrates is usually many times greater than the original value of a ton of the ore from which they have been extracted, and it is for the purpose of extracting this value from the concentrates that the chlorination mill is used. Assuming that the ore from which the concentrates came contained two and one-half per cent of sulphurets, then two and one-half tons would represent the product of a one hundred-ton mill; if five per cent, a fifty-ton mill, and if ten per cent, a twenty-five-ton mill. The cost of treating concentrates in these mills ranges from $8 to $15 per ton. Large gold mines frequently have their chlorination mill in connection with their stamp mill. The following description very clearly illustrates this process:

The ore treated is quartz, carrying free gold, pyrites, galena, chalcopyrite, arsenopyrite and zinc blende. It is first crushed in rock-breakers and then stamped fine enough to pass through a forty-mesh screen; then it passes as a slime over silver-plated copper amalgamating plates to the concentrators. The free gold is saved in the stamp batteries and on the plates; the sulphurets are collected by the concentrators. The latter are dried and then roasted, chlorinated and leached. The roasting is done in a reverberatory furnace. About one per cent of salt is added near the close of the operation. All the sulphur, arsenic and antimony are expelled, and the iron and other base metals oxidized. The gold is left in a free metallic state, the silver being partly concentrated into a chloride by the salt. The roasted ore is then transferred to chlorinating tanks, each holding from two to three tons. The covers are put on, and the joints calked with rags and luted with dough, to make the tank gas tight. The tanks have false bottoms, perforated with holes of suitable size and covered with sacking. Chlorine gas, made from salt, black oxide of manganese and sulphuric acid, is then introduced below the false bottom and allowed to permeate the ore. Two or three days are required for their permeation. The gold and silver is thus concentrated into chlorides. The chloride of gold is leached out by water added to the top, and drawn off at the bottom and run into precipitating tanks. The gold is precipitated in a fine metallic state by the addition of the sulphate of iron. The water is then run off, the gold collected and dried, melted in graphite crucibles and cast into bars. The silver chloride remaining in the ore is dissolved out by a solution of hyposulphite of calcium. The solution is run into other tanks, and the silver precipitated as a sulphide by adding calcium of polysulphide. The sulphide of silver is dried, roasted and then melted and cast into bars.



IMPROVED MILL FOR WORKING CONCENTRATES.

This mill can be built any size, the most common are of two and one-half tons and five tons capacity per day of twenty-four hours. This quantity is usually worked in three charges of about one or two tons, which require about eight hours' roasting. The Risdon Iron Works of this city have built a large number of these mills, and when in the hands of experienced men, ninety-five per cent of the value of the concentrates can be saved. Any inquiries to this firm for further particulars will be cheerfully answered.

NEARLY every paper published in a mining town on this coast advises mining claim holders that if they want to dispose of their property they must open it up, develop it, show what there is, or, rather, that there is a mine to buy. The advice is excellent, and continues to be repeated because it cannot be improved. Shiftless and unappreciative holders of mining "claims" which have never had any more work done on them than that up to Jan. 1st, '93, just sufficient to hold them, cannot expect to readily dispose of their property without first exhibiting that the property, if for sale, has some tangible value. But what shall be said of that numerous class who, holding "claims," would gladly develop them if they only had the money? No amount of well-meant advice, alone, will do them any good. Probably one way to aid in solving this matter would be to devote the space usually accorded to advising claim holders to develop their claims, to a plain statement of the fact that the price should be commensurate with their apparent merit. Too often the owner of a claim, developed or undeveloped, has his ideas set so high that he cannot find a market, because asking too high a price for his problematical property. The buyer and the claim owner can get together quicker where the latter does not demand nor expect an unreasonable price for his prospect. And, on the other hand, the would-be investor must needs recognize the usual percentage in favor of the game, remembering that risks, as well as profits, must be divided.

A FREEZE in Florida has boomed the price of California oranges. While regretting the loss to Florida, it is gratifying to know that any California product will command a good figure these dull times. But though oranges have temporarily increased in value, the fact hardly warrants the statement in the Oroville *Register* that oranges are "better than gold." No "freeze" in Florida or climatic disaster elsewhere would greatly enhance the value of the yellow metal, but, on the other hand, no overplus or competition in production can depreciate it. Not so with any other product. If oranges are "better than gold," it is of course possible that the orange growers will hesitate to exchange their product for an inferior commodity, and yet not wholly probable.

THE activity in mining so manifest in '94 is unabated. The interior papers are the best evidence of the pervading spirit, and in every direction are heard notes of preparation for work of development so soon as the weather permits. Old mines abandoned for years are to be reopened and worked under better economic conditions.

UTAH capitalists, realizing the advantageous opportunities for investment in California mining properties, are investing heavily in Siskiyou and Trinity counties. The North Fork Co. has been doing considerable on Coffee creek, in getting ready for the coming season. The property consists of 300 acres of placer ground, and is unworked territory.

THE recent telephone patent decision in the United States Circuit Court at Boston attracts national attention. In effect all forms of telephone receivers and transmitters are free; the patent on the use of the induction coil with the transmitter expires this week, so that there is nothing in the way of installing and operating private lines that do not involve the use of a switch board.

IT'S a pity that silver cannot be taken out of the domain of petty partisanship and given the prompt affirmative action that the times require. Each party seems "sparring for points," and more desirous to avoid than press action. Politics should give way in crises to public requirements, and the silver question is to-day the most prominent factor in the nation's financial status.

COLORADO makes an excellent showing in mineral production in '94. The gold output of the State for the year is $11,235,000, an increase of nearly $4,000,000 over '93, making it surpassed as a gold producer only by California. When it is remembered that the total gold output of Colorado in 1891 was only $4,764,880, and of '92, $5,539,021, it will be seen what strides the Centennial Commonwealth has made. Colorado's papers claim that had it not been for the Cripple Creek miners' strike last summer the aggregate of the gold yield for '94 would exceed that of this State, and look forward with confidence to '95 in this regard. It is not a matter of much worry one way or the other, and meanwhile, California congratulates her sister State on her magnificent recuperation from the disaster that threatened her when there was no silver lining to the financial cloud, and will continue to lead in the output of the yellow metal. Colorado's silver yield for the past twelve months aggregates in value, even at present low prices, $14,721,751, and though lead he quoted at but three cents a pound, the aggregate yield that State shows for the year is valued at $3,268,613. The State makes a grand showing and its enterprising miners deserve commendation.

Two Shafts on Mines.

A State law which went into effect March 16, 1872, ordains that "it shall not he lawful for any corporation, association, owner, or owners of any quartz mining claims within the State of California, where such corporation, association, owner or owners employ twelve men daily, to sink down into such mine or mines any perpendicular shaft or incline beyoud a depth from the surface of three hundred feet, without providing a second mode of egress from such mine hy shaft or tunnel, to connect with the main shaft at a depth of not less than one huudred feet from the surface. It shall he the duty of each corporation, association, owner or owners of any quartz mine or mines in this State, where it becomes necessary to work such miues beyond the depth of three hundred feet, and where the number of men employed therein daily shall he twelve or more, to proceed to sink another shaft or construct a tunnel so as to connect with the main working shaft of such mine, as a mode of escape from underground accident or otherwise. Aud all corporations, associations, owner or owners of mines as aforesaid, working at a greater depth than three hundred feet, not having any other mode of egress than from the main shaft, shall proceed, as herein provided. When any corporation, association, owner or owners of any quartz mine in this State shall fail to provide for the proper egress as herein contemplated, and where any accideut shall occur, or any miner working therein shall he hurt or injured, and from such injury might have escaped if the secoud mode of egress had existed, such corporation, association, owner or owners of the mine where the injuries shall have occurred shall be liahle to the person injured in all damages that may accrue by reason thereof; and an action at law in a court of competent jurisdiction may he maintained against the owner or owners of such mine, which owners shall be jointly or severally liahle for such damages. And where death shall ensue from injuries received from any negligence ou the part of the owners thereof, by reason of their failure to comply with any of the provisions of this act, the heirs or relatives of the deceased may commence au action for the recovery of such damages as are provided hy an act entitled an act requiring compeusation for causing death by wrongful act, neglect or default, approved April twenty-sixth, eighteen hundred and sixty-two."

The Technical Society.

The first meeting of the Technical Society of the Pacific Coast for '95 was held at its rooms iu the Academy of Sciences on the 4th inst. The event of the eveuing was the reading of a paper entitled "Pressure and Impulse in Motive Engines—a Look into the Future," by Mr. John Richards, M. E. It was a thoughtful article of unusual merit, and the propositions, theories aud statements were hacked up hy lucid logic and practical argument. In the absence of Mr. Richards, the paper was read by Mr. Andrew M. Hunt. Mr. Arnold D'Erlach presented some interesting notes on the "Latest Project for an Alpine Tunnel at the Simplon," accompanied hy a map of the proposed route. The proposed tunnel would be over twelve miles in length, costing, it is estimated, 60,000,000 francs.

The Nominating Committee of the Society reported a ticket for officers for the ensuing year, to be voted for at the coming election.

The proposition to participate in the puhlication of proceedings in the *Journal of Associated Sciences* was unanimously endorsed, and the directors empowered to take prompt affirmative action. The scheme to unite with the Mechanics' Institute is yet under discussion.

THERE have heen nearly a thousand devices patented for preventiug the ravages of the teredo navalis and the limnoria, hut none are wholly effective. A fortuue awaits the man who can successfully deal with those pests, which cost this coast alone nearly half a million dollars annually.

THAT "biggest gold miue" in New York, spoken of last week, is still heing worked. It is probahle another hig strike of ore 900 fine will he made about February 1st.

Tardy but Beneficent.

The last and greatest of the late Jas. Lick's puhlic henefactions is at length put into practical shape, and the purposes of the deceased philauthropist are in a fair way to he realized. The Lick Ohservatory, the California Pioneer Buildiug, the Academy of Sciences, the Key Monument, the free haths and minor henefactions have now added to their numher the California School of Mechanical Arts which was formally transferred to the school trustees on the 3rd inst. It cost $115,000, and the remainder, $430,000, has heen transferred to the credit of the school trust.

The building will accommodate 350 hoys aud girls, and is considered hy many to be Mr. Lick's best gift. Mr. A. S. Hallidie, vice-presideut of the school trustees, in an address ou the school, its province and purpose, said the founder's desire was recognized; that the school should graduate good artisans rather than professional men and women, aud that its benefits should apply to those whose expectations are to become first-class journeymen rather than superintendents, managers or foremen. It is intended that this school shall be a means to develop the hest obtainable results, and iu this the intent is to be practical, taking a middle position between the trade school and the manual training school, with effort to combine the best elements of hoth and trusting to experience for such change or modification as time may suggest.

The work is uecessarily experimental in some ways. The scope of instruction cannot practically induce all desirable elemeuts, but the intent is well shown in the following statement from Mr. Hallidie's address:

> The California School of Mechanical Arts will carry students to the point where they may be considered as well fitted to become first-class artisans. The groundwork of three years in general instruction, allied to mechanical pursuits, in which is included the usual education of an American boy or girl, and which will complement that of the common school, and the one year of special trade instructiou under practical teachers expert in that particular trade, will give an advantage to the graduate which will be difficult for others to overcome.
>
> While admitting that excellent workmen were produced under the old apprenticeship system, it was at an enormous economical sacrifice, and oftentimes at the expense of much personal self-respect. The time of a boy or girl indentured to learn a trade was considered the property of the master, and was often valued for its servitude, and not as an element of value to the apprentice, and the amount of drudgery performed under such conditions was appalling to an ambitious and independent mind. This school proposes to economize the time of the student and to give him such opportunities for advancement that it will be the fault of the student if he fails in making a fair amount of progress.

It may not he wholly out of place to suggest that, granting the fullest success to the practical intent of this admirable institution, it were a pity after such elaborate preparation and the arousiug of hopes and honorahle amhition in the mind of a student if trade conditions did not give a fair opportunity for their realization. The idea is a grand one. Thousands go yearly out of our public schools with their heads crammed and their hands empty, poorly fitted for the battle of life. This school proposes to give a young Californian a chance to learu a trade; to put something in the hands and the head that will be of life-long value if utilized, and the practical purport is to he warmly commended. With the commendation comes the reflection: What are the inducements in San Francisco to-day for amhitious youth to learn trades? What the prospect of remunerative employment when the deserving possessor of a trade is ready for such employment? There is no obligation, actual, tacit, or implied to furnish such employment, and yet the acceptauce and establishmeut of such a school carries with it an indirect assumption that results in actual life will justify and warraut the noblest effort on the part of the studeut therein.

The working results of the great industrial school, which begins under such favorahle auspices, will, of course, not be confined to this city, nor probahly to this State; the widening circles of intelligent lahor will he benefited to remote limits, but its greatest resultant good to the metropolis is bound up with the question of the progress of manufacturing industries in that city.

A NEVADA EXCHANGE says that in the viciuity of its publication office several claims were "jumped" after New Years. Auy oue holding a claim, who didn't think it worth while to have notice recorded as required hy that relief hill known as "the suspension of assessments," ought to have his claim jumped.

Concentrates.

OREGON PAPERS say that State will produce $3,000,000 in gold this year.

THE Davis estate has sold the Pacific mine, Montana, to Silas F. King for $90,000.

"NOT since '62 has there been such heavy and contiauous rain," writes a Tuolumne Co. subscriber.

WHILE digging a well a Helena, Montana, man got enough gold out of the dirt to almost pay for the well.

SALT LAKE is to have a mining stock exchange. Jos. Davis is now in this city getting points on how to run it.

THE Mohave Co., Arizona, *Miner* deserves credit for energy and faithful work in its field, which it completely covers.

H. MATTERN and G. E. Sackett, of Ashland, Or., have received a draft for ore shipped to the Selby Smelting Works. The rock went $240 per ton.

DURING the past year the Boston & Montana company has been employing nearly 550 men in Butte and producing from 15,000 to 18,000 tons of ore per month.

AT a meeting of the stockholders of the Anaconda Company, held in Butte Dec. 31st, the life of that corporation was extended to forty years from Jan. 19, 1891.

THE bill recently introduced by Congressman Caminetti regarding mineral lands will be amended to make its provisions include all the railroad grants in the State.

THE Truckee *Republican* reports a snowfall for the season at that point to Jan. 5th of 178.5 inches. In 1890, which was a year of excessive snow, the fall to the same date was 184.75.

HOT SLAG from lead blast furnaces is being used at the works of the Broken Hill Proprietary Company in New South Wales, Australia, to generate steam to run an electric plant.

THE case of M. W. Fox against the Hale & Norcross Mining Company, which involves a judgment for more than $1,000,000, will be called up in the State Supreme Court for reargument on the 21st instant.

THE Pacific Bureau of Mines Association of Portland, Or., has incorporated with a capital stock of $100,000, divided into shares of $1 each. W. T. Mendenhall, W. J. Lehigh, E. S. McComas and R. Glen are the incorporators.

THE MacArthur-Forrest people, through their representative, P. Geo. Gow, have made an offer to put up a cyanide plant in Bodie for crushing and working low-grade ores, they requiring a guarantee of a certain amount of rock.

THE *Central Nevadan* says a lot of giant powder was placed in the blacksmith shop at the Morning Star mine to thaw out. It exploded and blew the building to pieces. The report was heard at Battle Mountain, a distance of sixteen miles.

MESSRS. HAMPTON AND LEWIS cleaned up recently $27,000 from their mine situated on Tom East creek, Josephine Co., Or. Such a sum would not be had work for the year, but more than double that amount will be realized at the end of the season.

THE Good Hope Placer Mining Company, with a capital stock of $100,000, proposes to work the Good Hope placer, the Little John placer and the Mitz placer claims, containing eighty acres in White Canyon mining district, along the Colorado river.

Legh Harnett, the mining expert and writer who has been making a personal inspection of the Josephine county, Or., mines, gives it as his opinion that this coming season will see no less than sixty hydraulic placers at work in that county, large and small.

THE Premier of the colony of Western Australia stated in his Budget speech on September 24th: "The export of gold for 1890 was £80,664; 1891, £115,182; 1892, £226,284; 1893, £421,212; for the half of 1894, £288,281; and up to the 22d of last month, £496,975."

HENRY BRATNOBER, the well-known Montana mining man, is investigating the reported rich gold discoveries in the Coolgardie district, in Australia. In a letter to a Montana friend he says he is not favorably impressed with the mineral possibilities of that country.

THE Parrott Company will remove its smelting plant from Butte, Montana, to a point about fourteen miles from Whitehall, in Jefferson county, known as Point-of-Rocks. The company has secured 7000 acres of land there, and the water is sufficient for the purposes.

NEW YEAR'S DAY seventy-five members of the Miners' Union marched to the King Solomon mine, near Clancy, Montana, in a body, and induced four non-union men employed in the mine to quit work. Three of the men joined the union, and the other refused and left the camp.

THE La Noria silver mine in Mexico, in which Pennsylvania men have sunk $500,000 in cash, has been abandoned by the stockholders. It has been decided to sell the entire property at public sale in Pittsburg within thirty days to the highest bidder to pay off the indebtedness.

A. H. RICKETTS, chairman of the Committee on the Protection of Mineral Lands, yesterday sent to Washington a report which will be made amendatory to the Caminetti bill, showing in the aggregate, an additional 20,585,000 acres included to sundry land grants to railroads in California.

THE *Mining and Market Reporter* says that there is no mining State in the Union that has been more obnoxiously infested with the "wild cat" mining speculator and "wild kitten" mining man than Montana, and evinces a disposition to strangle the beasts.

THE old Keystone mill at Amador City was partially destroyed by fire last week, which will cause a delay of several weeks until it can be put in running order again. Although the building was not entirely destroyed, yet the damage done to the works will amount to several thousand dollars.

THE old, old question of apex and dip comes up again in a suit in Salt Lake City of Messrs. Denhalter and Hoffman vs. the Galena Consolidated Mining Company. The plaintiffs are the owners of a half interest in mining claims adjoining the Galena property, and claim $200,000 as their share of the proceeds of ore extracted from their claims by the Galena company from 1888 to 1890. The defense is that the vein from which the ore was taken has its apex in the Galena claim and that the plaintiffs have no interest in it.

THE Black Wonder Mine Co., of Sherman, Colorado, claims to have "just paid dividend No. 9," but those acquainted with the company and its methods say that the Black Wonder mine is not a dividend payer, and the payment of dividends is fraudulent and done to deceive innocent and prospective investors.

THE Alaska company at Pike City, Sierra Co., is running a drain tunnel in from the mill, which will tap the shaft they are working through, at the 150-foot level, just below where the most water comes in. They will use the tunnel to drain the mine and to run the rock directly into the mill, saving power and time.

"KEEP your eye on the mineral land bill," says the Anaconda *Standard*. The theory is nothing good can come out of the Fifty-third Congress, yet it is barely possible that, out of the wreck, the people of Montana may save a little something in the way of the rescue of the State's mineral domain from the Northern Pacific ring.

THE Mayflower Mining Company has served notice on the owners of buildings in Bath that from the 1st inst. $2 per month rent will be payable at the office of the company. The town is just east of Forest Hill, and was built at the works of the Breece & Wheeler gravel mine, at the surface line between the Mayflower and the Breece & Wheeler mines.

HAS the Idaho mine inspector been able to protect a single miner in the lower levels? asks the Cœur d'Alene *Sun*. If the office is continued, the coroner's jury in each and every instance of a mine accident from a cave-in ought to bring in a verdict of manslaughter against him for negligence of duty.

GEORGE GATES, proprietor of the sulphurets-saving plant at the Kennedy, Nev., is preparing to make another test of the cyanide process in the treatment of his sulphurets saved from the tailings. He gave the process a trial nearly two years ago, but the result was not satisfactory in the percentage of gold extracted.

THE *Tribune* publishes an elaborate review of the mining interests in Utah for 1894. Figured at local prices the output of lead, copper, gold and silver shows a total of nearly six and a half million dollars. Computing all the metals at their seaboard value it would increase the total to over eleven and a half million dollars.

REPORTS come to the Tombstone, Arizona, *Epitaph* from Plomosa of great finds in the placers. Lately two miners took out $117 in one pan. The Wilson Brothers have taken out $1 to the pan right along. There are 200 men in the district, and they are all doing well. Plomosa embraces about all the country between Ehrenburg and Harqua Hala.

J. B. WILSON, a Kaslo, B. C., merchant, who sent 4 oz. 3 gr. of local gold to the San Francisco Mint a short time since, has received returns. The gold went .837½ fine, with .153½ silver. The gross value of the metal was $68.20, and net value $66.95. This places the purchase value of Kaslo gold at about $17 an ounce. Some Big Bend gold is worth $18.50 an ounce in San Francisco.

AT a recent meeting of the Golden Feather Channel Co., Ltd., in London, Eng., it was announced that operations in the Feather river near Oroville were on the eve of a great success, and that it was expected rich returns would result from next summer's work. It was decided to reorganize the company under the name of the "Golden Feather, Limited," and an assessment authorized of one shilling per share.

THE Hailey, Idaho, *Times* says: The stamps of the Camas No. 2 mill were started up last Saturday. After running a few hours the plates began to show gold, and last night, after thirty-six hours' run, they were thickly coated. The other ten stamps are about ready, and will begin dropping some time this week. Until they do, miners say that the mill will make three to four tons of concentrates per day, worth between $70 and $90 per ton. This, besides what free gold will be caught on the plates.

THREE Utah doctors have organized the California Gold Mining and Milling Co.—Dr. Vincent, Dr. Dart, Dr. Bowers—and propose to work sulphide ores in Meadow Lake district, seven miles from Cisco. Five claims are owned, on one of which a tunnel penetrating 150 feet has uncovered a body of ore ten and a half feet thick, which varies in assay from $20 to $300 per ton. The district was famous many years ago. The M. D.'s may succeed in bringing the rebellious ores to subjection.

THE Siskiyou Gold Development Co. of Salt Lake City, Utah, has organized with a capital stock of $1,000,000. The incorporation consists of W. S. McCornick, president; A. Hanauer Jr., vice-president; John R. Middlemiss, secretary; James Glendenning, and D. P. Tarpey—these constituting the board of directors. The company has paid $50,000 for what is known as the "Porphyry Dyke," situated on the west side of the Klamath river, about five miles from Hornbrook, and will soon erect a large plant, a 100-stamp mill, it is reported.

THE McCauley G. M. & M. Co., of Gardiner, Montana, is putting in a twenty-stamp gold mill. The stamps weigh 850 pounds. The mortars are lined with copper to amalgamate as much gold as possible before the pulp passes through the screens. After being crushed at about forty mesh, the pulp flows over amalgamated copper plates in front of each mortar, then into a series of classifying boxes, and from these the different sizes are drawn off into a double deck round huddle of special construction, when the final concentration of the sulphurets is effected.

IN the two suits instituted in this city in 1891 by Theodore Fox, a stockholder in the Consolidated California & Virginia Mining Company, who charged J. W. Mackay, Senator Jones and other directors of the California & Virginia Mining Company with fraud in the management of the California & Virginia property, Judge Seawell has sustained the demurrers entered by defendants as to all but one point, thus throwing out of court all the charges save the one that Mackay, Jones, Flood and others, as managers of the California & Virginia mine, sent the ore from the mine to the works of the Comstock Mill & Mining Company, which they owned, to be crushed and milled at an exorbitant rate. A further hearing on this point will be had.

THE Butte *Independent* says there is a remarkable young woman who resides in Lump Gulch, who certainly made a great record for herself. She is very strong and energetic. During the last few months she has helped sink a twenty-three-foot shaft upon a very promising claim in which she and another party are interested. She did all the shoveling connected with the work. In addition to this the enterprising young woman has sawed 100 cords of wood, kept boarders and assisted in various other enterprises. The young men will be glad to know this prodigy is unmarried.

H. T. STRATTON writes from Alaska that the gold field there is probably larger and richer than any now being worked in the world, but there are many drawbacks in climate, the high price of provisions, lack of transportation, and that only a stalwart man physically can endure the strain. He says: "This is no country for weak lungs. Not a man in twenty will endure the hardships for one season for any sum of money he is likely to make in ten. I can hardly think of a man of my acquaintance that I would advise coming. No one but a thoroughly seasoned prospector and camp-man has any business here at all."

THE excavation for the underground hoist at the Roanoke mine near Mokelumne Hill, Calaveras Co., is done and the plant in position and ready for work. The excavation is 7x30 feet in the clear, timbered by eight-inch spruce timbers and lagged with two-inch lumber. A force of men was put to work on the top sinking; another force worked up from the excavation. They met about the middle with a variation of less than half an inch. The shaft from the hoisting plant is down to a depth of fifty-five feet, and the rock is very rich. This underground water-power hoist is a novelty, the only thing of the kind in the county. Without it water power could not be used at the Roanoke mine.

AN outgrowth of the sale of the Mountain Lion and the Ohio mining claims in Siskiyou county last November by Thomas Morcom, a citizen of this State, to H. W. Brown and some of the Mercur, Utah, stockholders, for $50,000, is a quarrel over a portion of the purchase money. Andrew Rahbitt, who claims to be entitled to one-third of the net proceeds of the sale, says that Morcom is endeavoring to defraud him out of a portion of his share. A part of the purchase price was paid at the time the mines were bought, and of this Babbitt says he received his proportion. A note for the balance due, payable on May 14, 1895, was given by Brown, and on this $7000 was subsequently paid. About a week ago the note, on which $10,500 was yet unpaid, was discounted at the bank of McCornick & Co., in Salt Lake, for $8000, through Louis Green, acting as attorney-in-fact for Morcom. Being apprehensive that he is not to be paid $2300, which he claims is yet due him on the deal, Babbitt filed an attachment suit against Morcom. A writ was issued and a levy made by the sheriff on cash supposed to be the money paid by the bank on the Brown note.

State Constitutional Amendment.

TO THE EDITOR:—Regarding the query "How will the amendment of Section 17 of Article 1 of the State Constitution, which reads as follows: 'Foreigners of the white race, or of African descent, eligible to become citizens of the United States under the naturalization laws thereof, while *bona fide* residents of this State, shall have the same rights in respect to the acquisition, possession, enjoyment, transmission and inheritance of all property other than real estate, as native-born citizens; provided, that such aliens owning real estate at the time of the adoption of this amendment may remain such owners; provided, further, that the Legislature may by statute provide for the disposition of real estate which shall hereafter be acquired by such aliens by descent or devise;' affect alien ownerships of California gold mines," I will say that in my opinion the effect of the recent amendment in so far as it touches this question will be to restore the common law disability as to real estate acquired after its adoption by aliens who are *bona fide* residents within this State; and that non-resident aliens rest under no other or greater disability now than before said amendment was adopted, unless Section 671 of the Civil Code of California (which took effect July 1, 1874) and which provides that "Any person, whether citizen or alien, may take, hold, and dispose of property, real or personal, within this State" be unconstitutional, which I do not think is the case, as the Legislature does not seem to be disahled from extending or adding other rights on non-resident foreigners by the amendment under discussion.

Yours faithfully, ALFRED HERBERT RICKETTS,
Attorney and Counselor at Law.

San Francisco, January 10, 1895.

Personal.

MR. A. E. ROBERTS has returned from a visit to the South African gold fields.

M. BUCKLEY succeeds Geo. F. Kellogg as superintendent of the Hope mine at Basin, Montana.

J. V. KEELEY, owner of the Clementina mine, Yellow Pine district, Lincoln Co., Nev., is in the city.

C. A. LILLY, foreman of the California mine in Eureka district for a long time, has been appointed superintendent of the Eagle Bird mine at Ormonde, Nevada Co.

Obituary.

JONAS H. WALKER, formerly associated with Mackay, Fair, Flood and O'Brien in the Comstock deal, died in poverty in this city on the 3d inst. Walker accumulated millions and went to Philadelphia in 1872. He lived luxuriously and entertained lavishly. His millions were lost in unfortunate speculations in railroads and stocks. He tried to retrieve his fortunes in this city, but luck was against him, and a few days after his former colleague, Jas. G. Fair, left this earth and $30,000,000, he passed away with not the slightest likelihood of there being any litigation over his estate.

Improvements in Matte Smelting.

Written for the MINING AND SCIENTIFIC PRESS by HERBERT LANG, Seattle, Wash.

The essential condition of pyritic smelting is the maintenance of an atmosphere in the blast furnace oxidizing not only toward carbon, the customary fuel, but toward certain ores as well. In other words, there must be an excess of oxygen above the amount necessary to burn the coke or charcoal, to react upon the oxidizable parts of the ore charge. Thus, pyritic smelting burns ore as well as carbon, and produces at one operation the effects which are usually gained by the two separate ones of roastiug and smeltiug. The substances which serve the purposes of pyritic smelting are the oxidizable minerals, or such as are commonly roasted iu other processes, belonging to the classes of sulphides, arsenides and antimonides, embracing pyrite, pyrrhotite, chalcopyrite, blende, mispickel, and very probably galena. To these may be added, in due course of experience, the remaining native minerals of these classes. We may make use of any substance which, by melting down, produces matte or speiss. These, be it noticed, are the substances which have been regarded as conferring upon ores their refractory quality; whence we may say of pyritic smelting that it consists in burning the refractory and heretofore difficult elements of ore, it being practically found that the most injurious combinations, when viewed from the standpoint of other processes, are the most docile to pyritic smelting. I would not be understood as claiming for this new art anything which does not rest upon intelligent experiment, and therefore I will limit the above assertion as to the availability of the process in treating refractory ores to just those combinations which have been the subject of experiment, namely, to pyrites and, to a less degree, those ores containing blende and chalcopyrite.

NATURE OF THE OXIDIZING FUSION.

Every one understands the ordinary carbon reduction smelting (smelting by carbon reactions) and the function of fuel as producing heat, but there are results of the fusion which are not generally understood. Let it be borne in mind that no volatilization of sulphur or arsenic, nor any oxidation of iron or other metal is to be expected when we fuse with carbon alone. If we melt down any of the long list of sulphides, arsenides, etc., which, for convenience, I call the matte formers, we will get an amount of matte almost equal to the original material charged, and consequently there can have been no concentration of the values in a smaller mass: that is to say, no enrichment of the product. We have, therefore, gained little or nothing by the operation, when carried out with a charge largely composed of matte formers, excepting those advantages which are incident to all forms of smelting alike, namely, the slaggiug of the earthy substances and the volatilization of the first sulphur equivalent in pyrite. This, the reducing fusion for matte, when it is applied to the extraction of gold, silver and copper from their ores, is generally known as plain matting, and by some, including the writer, is styled the German system of matte smelting. It is always carried out in blast furnaces. As far as the present inquiry is concerned, the significant feature of the German system is the reduction of metallic oxides and the preservation of sulphur and arsenic combined with the heavy metals as matte. Furthermore, the same mixtures which in the presence of those elements give rise to mattes, in their absence produce metals or metallic alloys. Later I will show how the pyritic processes produce opposite effects; how they produce metallic oxides, eliminate sulphur and arsenic, and how the conditions are adverse to the production of metals or alloys. We may say that the efficacy of the German system of smelting by carbon reactions decreases as the proportion of matte formers increases, while that of the pyritic system increases with the increase of the matte formers. We have degrees of pyritic smelting, varying in intensity from the slight pyritic effects noticed in copper matte furnaces, where a small percentage of sulphur is volatilized and by inference a corresponding amount of oxides formed and scorified, up to the powerful effects of the hot-blast acting upon solid masses of sulphides, and consuming them as coal is consumed under the forced draft of a man-of-war.

There are two divisions of pyritic smelting which, for convenience, may be called the Austin process and the gradual reduction process. The former is characterized by the sudden combustion or fusion of the components of the charge, the latter by their gradual heating, and the oxidation and subsequent fusion of the matte formers. In the latter the furnace is fed in the ordinary way, the compounds being added in layers alternating with the fuel, while in the former special arrangements are made by which the combustible ores are fed directly into the zone of fusion, which they reach in a cold state, with their fuel value unimpaired, which ought to be a valuable characteristic. Advantageous as this proceedure would seem to be from analogy, experience does not bear out theory, and the device which accomplishes the central feeding has been abandoned in favor of layer feeding, which is now in vogue at various existing plants. We need, therefore, not discuss further this peculiar practice, which would seem to have sunk into disuse, but will proceed to a consideration of the gradual reduction process.

Under ideal conditions prevailing in the pyritic furnace the following train of effects is produced: The ideal charge, consisting of matte formers, together with just sufficient silica to slag the oxides expected to be formed, is fed in layers upon the cold top of the preceding charge. I say cold top, for from a hot top we infer (*a*) a serious loss of heat; (*b*) a loss of metal by volatilization, intolerable in any process. As the charge sinks in the shaft, it rises in temperature by the absorption of heat from the ascending gases, until a point is reached where the gases, oxidizing of course in the ideal, begin to react upon the matte formers—that is to say, they begin to roast them, convertiug sulphur into sulphur dioxide, arseuic into arsenious acid, and the heavy metals iuto oxides. A second source of heat, namely, that resulting from local chemical action, is now added to the first named source, and the reactions ensue with increased energy. We may infer a gradually increased intensity of chemical action from the moment the charge is fed into the furnace, or from where it reaches a perceptibly heated location iu the shaft until it becomes fused and its components separated in the fusing zone. We may also iufer a production of matte at a considerable elevation in the shaft, certainly much above the locality customarily called the zone of fusion. And we must infer the very extensive combustion of the matte as it trickles downward through the partially melted charge, all the time in contact with gases which carry an excess of oxygen.

Of moisture and carbonic dioxide the elimination is complete. Sulphur is eliminated as sulphur dioxide, and to some extent as sulphuric acid. Sulphur which escapes oxidation goes to form matte. Arsenic is volatilized as arsenious acid more freely than sulphur, but a portion remains as speiss. Antimony we may allowably conjecture to behave as arsenic; but in the absence of experimeutal observation we may dismiss the matter at present. Sesquioxides of iron and manganese are reduced to protoxides, presumably through the influence of the molten matte, upon which they have a decided reaction which may be typified thus: $Fe_2O_3 + M_2S = 2FeO + M_2 + SO_2$.

These as well as other metallic oxides, those formed in the furnace as well as those naturally occurring in the ore, are scorified by the silica of the charge and added to the slag. I present herewith a tabulated resume of the changes which occur to the substances which constitute the usual smeltiug mixtures, premising that the general accuracy of the statements embraced within it depend upon the degree of oxidation taking place at the particular moment, which must neither exceed nor fall short of the requirements of commercially successful work; which is to say that only enough sulphides, etc., must be left unburned to furnish matte for a good extraction of the valuable metals contained in the mixture. When copper is worked for the proportion of sulphur required to form the matte is necessarily large, the matte itself generally reaching twice and often thrice the weight of the copper. But in precious metal smelting, and when the copper and lead are present if at all only in small proportions, the matte is, or rather should be, formed in much smaller amounts. Even as small a proportion as one-fortieth of the charge did good service experimentally at Mineral, while five per cent or one-tweutieth was regularly made whenever the ore admitted of so high a concentration. I am not aware that in treating heavily sulphureted ores so high a coucentratiou has ever been effected, but I do not consider pyritic work satisfactory that fails in puttiug at least ten tons into one, when dealing with ores that carry less than five per cent of copper. With ores practically free from copper, such, for example, as the gold-bearing concentrates from the California mines, I see no reason why a conceutration of twenty iuto one would uot be practicable, although the use of such material would of course involve brickiug as a preparation for smelting, and very probably the addition of copper ore to a small extent to secure a complete extraction of the gold. I gather from experience and observation that the matte, to effect a reasonably complete saviug of the gold and silver, should have at least twenty or twenty-five per ceut of copper; but with more acid slags than I have used I am informed that none is necessary. I conclude, from data furnished by others, that too high a percentage of this metal acts prejudicially upon the silver extraction.

EFFECTS OF THE OXIDATION OF SULPHIDES.

It is worth while for the sake of clearness to go over the ground a little more fully as to the functions of sulphide ores and matte formers generally in the pyritic furnace. These functions are three. First, we get heat by their combustion, which assists the reactions and helps do the smelting; second, we get flux out of them to take up the silica; and third, what is left of them melts down as matte and saves the valuable metals in the whole charge. Notice how intimately the three functions are connected, and how they are related. The heat produced accords with the amount of ore (sulphides, etc.) burned, and so does the amount of flux produced. The more heat, the more flux; but the more combustion of ore, the less production of matte. Consequently, the greater production of heat and flux from this source, the less matte we get. Again, as the elimination of valueless matters is the object of smelting, the less matte we get, as long as it is sufficient in quantity to absorb the metals that we seek, the better it is for us. Therefore, a highly concentrated matte is always to be sought, and our operations are successful in proportion to the concentration of the materials.

The questions that now arise are: How much available heat does the burning of the ore give? How much flux and of what sort is produced? And how much matte is ordinarily left? The experience thus far had in pyritic work does not supply entirely satisfactory answers to these queries, but we can approach reasonably close to satisfactory answers if assisted in some cases by reasonable conjecture. It was for a long time maintained by Mr. Austin, the real inventor of pyritic smelting, that enough heat is given out by the internal combustion of a fairly favorable charge to smelt it. It is, in fact, claimed that, with a highly heated blast (the indispensable adjunct of the extreme degrees of pyriticism), charges were smelted and the furnace continuously run without inside fuel excepting the combustible parts of the ore itself. But this achievement, while prodigiously gratifying to metallurgists and in every way commendable and praiseworthy, has not proved thus far the forerunner of recognized practice, and there appears to be no locality where the pyritic work is carried on in that manner. The result of the vast deal of experimenting and practical smelting which has been done within five years in pyritic furnaces is not to smelt without fuel, but to smelt with a smaller

COMPARISON OF SMELTING EFFECTS.

SUBSTANCE.	GERMAN SYSTEM.	PYRITIC SYSTEM.
Quartz	Scorified.	As in German system.
Alumina and its compounds	Scorified.	As in German system.
Limestone	CO_2 volat. CaO scorified.	As in German system. As in German system.
Magnesian Limestone	CO_2 volat. CaO, MgO scorified.	As in German system. As in German system.
Lime, Magnesia, Baryta and their silicates	Scorified.	As in German system.
Heavy Spar	SO_2 (SO_3 ?) volat. BaO scorified. BaS enters matte.	SO_3 volat. (conjectural). BaO scorified. $BaSO_4$ fused, eliminated with basic slag.
Iron Pyrites (Pyrite) (Pyrrhotite)	S, volat. FeS matted.	SO_2, SO_3 volat. FeS matted. FeO scorified.
Iron-Copper Sulphides (Bornite) (Chalcopyrite)	(Cu Fe)S formed and matted.	(Cu Fe) S matted. FeO scorified.
Copper Carbonates and Oxides	Copper enters matte as Cu_2S.	As in German system.
GOLD *in any form*	Enters matte as sulphide (?); recovery complete.	As in German system. Recovery complete.
SILVER *in any form*	Enters matte as sulphide.	As in German system. Recovery probably decreases as pyritic effects increase in intensity.
ZINC BLENDE	Part enters matte. Part decomposed— ZnO enters slag Zn volatilized. S volatilized.	Largely decomposed. Zno scorified, part volatilized. SO_2, SO_3 volatilized.
GALENA	Enters matte as PbS or Pb_2S; recovery of lead complete.	Mainly decomposed. PbO scorified. SO_2, SO_3 volat. Recovery of lead incomplete.
ARSENIDES and SULPH-ARSENIDES (Mispickel, Lollingite, Leucopyrite, etc.)	Arsenic slightly volatilized; remainder fuses with metals of group 4, as arsenide matte (speiss).	Arsenic chiefly volatilized. Iron oxidized and scorified.
COBALT and NICKEL	Enters matte to the exclusion of iron, but are excluded by copper. In presence of arsenic enter speiss. Recovery complete.	As in German system.
METALLIC IRON	Taken up by sulphur, forming matte. Scorification trifling.	Oxidation complete. Scorification of resulting FeO. Smelting temperature produced, and process assisted.
LEAD, *as Oxides and Carbonates*	Matted as sulphide. Recovery perfect.	Mainly scorified. Part may enter matte. Recovery imperfect.
MATTE (Fe Cu, Ag, Pb, Co, Ni), (As, S)	Fuses unchanged.	Part oxidized. Separation of As as As_2O_3; S as SO_2; Fe as FeO; Pb as PbO; fusion of remainder as (Cu, Co, Ni, Au, Ag) S. Oxidation (and concentration of matte) proportional to intensity of pyritic effects. Losses of lead and silver probably dependent on composition of resulting second matte.
COKE CHARCOAL	Incomplete combustion. Products CO, CO_2 in various proportions.	Complete combustion. Product CO_2.
COAL	Distillation of volatile constituents. Incomplete combustion of fixed carbon. Calorific effect limited.	Combustion probably complete, and calorific effects satisfactory (conjectural).
WOOD	Distillation excessive. Very slight smelting effects.	Combustion tolerably complete. Temperature may be sufficient for smelting, especially if aided by the hot blast.

proportion of carbonaceous fuel than any other smelting process has ever used or can use. This is not to say that all plants which claim to run on this system really so smelt, for I have information to the effect that at least one of the Colorado pyritic plants uses fourteen per cent of fuel; but this is not pyritic smelting, nor is it possible with such extravagance of fuel to achieve any desirable pyritic effects. With better management, the use of four or five per cent of coke, supplemented by the warm blast, has proved sufficient to fuse charges of ordinary difficulty, containing ten to twenty per cent of sulphur combined with iron and copper, producing a low-grade matte. The work in the Austin furnaces has been directed toward the beneficiation of heavy pyritous ores, high in sulphur, with the result of showing that such ores may be more profitably treated by pyriticism than by the rival process of lead smelting. But it also appears that the original plans of work, namely, the practice of central feeding of the sulphides to obviate sticking to the walls, and perhaps other devices recommended by the inventor, have not been found advantageous and have been discarded. The heated blast, which at first was held as of prime importance in pyritic work, appears to have fallen from its high estate in Colorado, and I hear now of furnace managers who condemn its use entirely. But in this I think they are entirely in error. Time, I think, will show that the greatest error of those who have exploited the Austin process is the practice of swift running. A great deal has been said about the daily capacity of pyritic furnaces and about the consequent saving of time and labor. Now, the essential thing is not to crowd a great lot of material through a furnace, but to do good work on what you have. Pyritic work of a thorough kind is inconsistent with fast running. Pyritic work is essentially slow. The claims of inventors that the use of smaller furnaces saves labor is the veriest bosh, inasmuch as it costs exactly as much to feed ore into and take slag away from a small furnace as it does from a large one; and the cost of a large furnace is but a mere trifle above that of a small one—a sum so small as to cut no figure in the cost of a plant. As regards the concentration of product by the one and the other, a small furnace—say of fifteen square feet hearth area—may be driven to smelt seventy-five tons of heavy sulphides per day, but the greatest probable concentration of product in such a case would not be above five into one. Now, if by using a furnace twice as large and driving half as fast we get a concentration of ten into one on the same amount of ore smelted, who can for a moment deny the economic superiority of the slower rate of running, especially as this would be achieved at merely the extra expense of furnace construction, say of $200 or $300?

The results obtained by myself at Mineral, Idaho, in smelting charges of argentiferous (and slightly cupriferous) sulphides, bear out in full the assertion that slow running is essential in pyritic work. The ore carried as high, at times, as twenty per cent of sulphur, always produced very fusible slags, and the charges the highest in sulphides were melted with the expenditure of six and one-fourth per cent of Connellsville coke, with a ratio of concentration of about ten into one. This was done with the unheated blast under circumstances that convince me that with moderately heated air, raised to the temperature say of 400° F., the fuel expenditure could have been diminished one-half. But notice the conditions that have to be maintained in the furnace: There is no surplus of heat to spare; the slag is only hot enough to secure its separation from the matte; the rate of running is not over two and a half tons in twenty-four hours to each square foot of hearth area, and the furnace is always in imminent danger of freezing up. But little matte is formed and it is likewise far from hot, besides being (a consequence of the considerable degree of concentration) quite rich in copper and therefore tends to build up the crucible with solid matter. The smelting was done in a water jacket; it should have been carried on in a brick or stone stack with walls at least two feet thick, in order to avoid the loss of heat, the more so as in smelting at this slow rate and with so little fuel and excess of heat, there is not the slightest tendency to corrosion of brick walls and consequently no reason to employ jackets. The same reasoning applies equally to most forms of pyritic smelting, wherein I am satisfied that the use of water-jacketed surfaces is a great mistake. Smelting at this slow rate brings about some conditions injurious to the process, in that the crucible or fore-hearth are liable to chill up, and a rate of running slower yet will put an end to the operations. In order to continue slow running, with its attendant high concentration and cooling of the hearth, it is necessary to return much matte to the charge, the action of which is to heat up the crucible and render tapping easy, while its combustion, which takes place to quite an extent each time it goes through, effects a desirable enrichment of the substance itself, while providing a proportional amount of metallic oxides, which immediately enter the slag, increasing, as a rule, its fusibility and liquidity. Even in lead smelting, where no chemical action of this sort can be expected, it is not uncommon for the furnace men to feed "iron" (matte) in order to, as they express it, "warm up the bottom," the effect being to transfer heat from the upper to the lower part of the furnace. If, then, such an effect is produced by the mere melting and passing through of matte (and any very fusible substance will have the same effect), how much the more effect the operation must have where a decided oxidation takes place during the downward passage? I am convinced that the regular feeding of matte as a part of the charge will be a recognized part of pyritic smelting when a further concentration is desirable, when the process languishes for want of heat and when the condition of the bottom demands attention. The matte, in order that its sensible heat should not be sacrificed, should be fed in a hot, that is to say, in a molten condition. This device, on which I have taken out letters patent, reaches its highest usefulness in the case of difficultly fusible mixtures, where the fuel supply is too low to properly melt the charge. When the furnace is fed low, so as to bring the fire near the top, and when an excess of oxygen finds its way through the charge, the matte is tapped from the crucible or fore-hearth and elevated to the feed floor and poured into the furnace in a thin stream which breaks up into particles which are scattered over the surface of the ore and find their way down the interstices. A portion is burned, producing heat and flux, and the remainder sinks into the crucible again, transferring to that part of the furnace the heat which is required to keep it in good working condition. I think that metallurgists may rely with entire safety upon this plan as fulfilling the functions for which it is designed.

HOT AND COLD BLASTS.

Heating the blast confers two principal benefits: First, economy of fuel; and, second, the improved working of the furnace. Both are very important indeed, and well nigh indispensable where fuel is costly, or where the slags are difficult of fusion, or where the matte formers predominate in the smelting mixture. There are two principal ways of heating the blast: First, by means of fuel burned outside the furnace, in a special firebox, by which the air for the blast is heated in pipes under pressure as in iron manufacture, as has been practiced in the several Austin plants; and, second, according to the plan that I have proposed, wherein air contained in a confined space, but not necessarily under pressure, is heated by the waste heat of the slag which has issued from the furnace and is on its way to the dump. My method has not yet been put in practice, and I make no claims or assumptions concerning it; but it appears to me that a temperature of at least 500° F. should be got by this means at no expense whatever, excepting interest on cost of plant, and trifling wear and tear. One thousand degrees can be attained by means of the pipe stove, and between the two systems the question would be as to the balance of advantages between 500°, which cost nothing, and 1000° got at the expense of fuel, labor and repairs.

INTERNAL FORM OF FURNACES.

The interior form of the shaft exerts an important effect upon the smelting process. Narrowing the smelting zone in the neighborhood of the tuyeres so as to concentrate the chemical action assists in a remarkable degree the reduction of oxides and the production of metals. Accordingly, we find furnaces designed for the production of metallic lead, copper and iron constructed with boshes as a rule, or at least diminished in size toward the lower part, a common type being the jacketed copper stacks used in Arizona, which are inverted frustra of cones. Furnaces of such form were at first used for pyritic work, and, singularly enough, are still recommended for the purpose by some individuals. The proper form, however, possesses vertical sides, as a little reflection will have shown the reader. With such a construction we get a diffusion of the blast through a greater mass of the charge, and consequently enlarged opportunities for the passage of uncombined oxygen upward from the tuyeres into the region where the heated sulphides are ready for combustion. We also get, it is true, a lower working temperature without than with the boshes or inward tapering sides, and this seems at present a real drawback to the process, for it compels us to use slags of lower fusing point, though this we may possibly obviate by the use of the heated blast.

It is matter of common knowledge, also, that the height of the furnace shaft exerts an influence on the action, those furnaces with the higher stacks effecting the greatest reduction of oxides. We therefore reason that the pyritic furnace should be low. Our reasoning is borne out in practice, and it seems to the writer that a greater depth of charge than four feet, or possibly five, with ordinary charges is a grave mistake. Again, inasmuch as the oxidizing influences are at work along the sides only, not extending far into the center of the mass of ore, it appears that the capacity of the furnace will depend upon the interior length of its walls. In designing a furnace for a given output, therefore, the question is rather one of the peripheral extent of the structure than of tuyere area.

LOSSES IN PYRITIC SMELTING.

There are, as usual, three principal sources of loss, namely, (*a*) loss in slags, (*b*) loss in flue dust, (*c*) loss by volatilization. Regarding the first two, there is no more to be said than that they exist to the same extent as in the German system and in lead smelting, and have the same effect upon the percentage of extraction of the precious metals. I will therefore dismiss this part of the topic by saying that the pyritic slags are as free from precious metals as those made by the lead and copper matte smelters, and are as free from copper as the latter habitually make.

Regarding volatilization losses we are somewhat in the dark. It is unfortunately the case that most of those who have practiced pyritic smelting, and particularly those who have exploited its processes, have left us in ignorance of the losses suffered in their work. Only rumors and unacknowledged statements concerning the work in the Rocky mountain region are at hand to base our estimates and conclusions upon, and these emanate largely from lead smelting people, some of whom are inimical to pyritic smelting as a rival to be feared. I will therefore say no more of the work in that region than that we have good evidence of its success in one locality, where a plant continues in operation though surrounded with lead smelters. Its losses, therefore, cannot be great, and most probably reach no higher percentage than its neighbors. Another pyritic works, running on difficult charges of zinc-bearing ore, are said to have suffered a loss by volatilization of eighteen per cent of its silver. We are further informed that "fire tops" always prevailed at this furnace.

In a campaign of three weeks at Mineral, the furnace treating a variety of mixtures and producing a concentration at times of forty into one, the combined slag and volatilization losses amounted to 15 per cent—a result due in part to overmuch experimenting in unknown fields of research. In another campaign in which 1800 tons of ore were smelted, my losses footed up 11 per cent of the silver, part of which I ascribe to volatilization in the furnace, part to the unavoidable losses in slag, and the remainder to the experimental bessemerization of a part of the matte. These intolerable losses were experienced under circumstances that suggested the causes and the remedies; and the latter being employed, the losses were subsequently largely obviated. Without going into the remote causes of volatilization of silver, I have only to say that they are mainly controllable by furnace manipulation, experience showing that they may mostly be checked by merely running with a cold top. Hot tops in any furnace smelting lead or silver ores are a potent cause of losses, but do not, as it appears, cause the volatilization of copper or gold. Compare the heavy discrepancies mentioned with later results at Mineral, where with more experience but less tractable ores the savings reached 95, 97 and 102 per cent of the silver in different campaigns. The latter result, unexpected but not unprecedented, serves mainly to emphasize the inaccuracies of assay methods.

Bartlett, in that form of pyritic smelting known as the zinc-lead process, finds that he sustains a loss of from six to fifteen per cent, varying, I presume, in accordance with the intensity of the pyritic agencies in use at the time. In this process a large part of the charge is intentionally volatilized, and the conditions of the work appear to be such as to render heavy losses unavoidable. Indeed, it seems to me remarkable that they are so small.

I will conclude these remarks upon the subject of silver losses by recalling the fact that the experience of those engaged in bessemerizing copper mattes is that the losses of silver are very large, so large, it would seem, as to preclude the use of that process for the treatment of most argentiferous mattes. At the same time the losses of gold are quite slight. Both these results correspond with what we might have expected from our knowledge of the habits of the two metals.

CONCLUSION.

Pyritic smelting to-day lacks nothing in conception or in principle or in scope of usefulness. What it lacks is chiefly the effort of scientific adepts and of skilled operatives, the one to make known its underlying principles, the other to carry on its practice. Thus far but few men have become educated either in its principles or its practice, and there is and must be a vast amount of misdirected effort, the result of which is inconclusive, and in the eyes of the world can only serve to confirm the doubt with which all new processes are received. In popular estimation pyritic smelting is a "patent process," the property of one man. In fact, it is an immensely broad conception whose important and indispensable features have not been and cannot be patented. In looking over its almost boundless field it seems to me that its most profitable immediate application is in the treatment of difficult ores in isolated districts, in fields altogether new, or supplanting in older localities less effective processes. With the improvements that have taken place in smelting in general, and with the increased range of usefulness of the matting processes in particular, there is every reason to expect that matte smelting will indeed supplant in the not distant future (*a*) those processes which fail to yield a high percentage of metal, (*b*) those which, like amalgamation, afford no valuable by-products, and (*c*) those which, like lixiviation, require costly preliminary experimentation and give an uncertain yield.

Gov. Budd.

"Jim" Budd was inaugurated Governor of California last evening with imposing ceremonies. Herewith is presented a good picture of the man who has been chosen by the commonwealth to fill the chair of the chief executive for the next four years. At the last session of the California State Miners' Association Gov. Budd was present and made an address, which went far to justify the belief of the miners that in the new Governor they would find as good a friend and fair an ally as they had in the retiring State executive, Gov. Markham.

HON. JAMES H. BUDD, GOVERNOR OF CALIFORNIA.

An Interesting Reminiscence.

A good many old timers in California who remember John Conuess, now living in Boston, Mass., will read with interest the following. Writing to an old friend in Tuolumne Co., Mr. Conness says:

Once in my California life I invested in one of the rich mines on Amador creek, where Hayward obtained his first fortune. He was a placer miner in El Dorado, near where I lived. At that time there was one stamp mill in place and at work on Amador creek. It was of an English pattern. The shafts of the stamps were square beams of wood, not less than eight or ten inches square, and the cams ran into mortises in the shafts, by which the stamps were lifted. I was one of two appointed by our company to go to San Francisco and have a mill made to work our lode. Observing the Amador mill work and noting its clumsiness, and, afterward, on the way down the Sacramento river on the steamer Confidence, observing what are called the lifting rods of the engine rise and fall through metallic boxes, smoothly and wholly without friction, I adopted the plan of having the shafts of the pestles made of iron, turned smoothly, and run in metallic boxes, like those on the engine of the steamer Confidence. A shoulder was keyed on the shaft or lifting rod, so that the cam could lift readily; but as the shaft or rod was round, and so that the lift might be done by a hold on both sides of the rod against the keyed shoulder, we had the cam made with two arms instead of one, just like two of your fingers. The mill was erected and it worked beautifully.

Now, one of the difficulties of the English-pattern mill was that the stamp rose and fell perfectly straight. It worked between two heavy beams of wood, which were horizontally placed to keep the rise and fall of the pestle within its narrow bounds. The result of this was that the ore or rock would get into the angles of the mortar and the faces of all the pestles would become worn unevenly, and, finally, either side of a pestle would look like a wedge and fall with a thud, not doing its work of pulverizing the ore. The pestles were constantly being removed to be cast over, and as often wearing unevenly on their faces.

Our mill being round and swinging a little to the right and left, and, as you will see, having no lateral beams keeping square pestle rods rising and falling perpendicularly, was a great improvement on the face-wearing plan, which was seen at once. But one day one of the cams lost one of its forks, or fingers by breaking off at the junction and, at once this stamp, while it raised with perfect ease, had an increased swing, rotating from one side to the other, and its face, having an equality of wear, did its work beautifully. There was no crowding of the ore from one side of the mortar to the other; it was a mechanical revelation. We had all the cams made with one finger, or wing, and did more for quartz mining than was ever accomplished in any other way.

Our company employed one of its members—a lawyer—to superintend and do the work. There was neither let nor hindrance to his management, but in a year or two we closed up the mine, assessed ourselves, paid the debts, and quit. A. H. Rose took the mine afterward and made a great fortune out of it. I had much experience in mining and put a good deal of money in it, and what I learned was that the best mine in the world could be frittered away, for want of good judgment in its management.

* * * * * JOHN CONNESS.

Mining Reports and Mine Salting.*

By WALTER McDERMOTT.

Mining Reports.—Some apology, or at least explanation, seems called for in the introduction of this paper; for, while the subjects treated are of interest to all engaged in the mining business, they become more or less personal in character when written on, and tend to drift into the form of a lecture. Should these objections become too apparent to the members, they will perhaps exercise a proper toleration in view of the fact that we have with us not only associates whose age precludes any lengthy practical experience, but also students who have still perhaps to go through somewhat the same experiences as are referred to in these notes. It has been my fate during the last twenty-three years not only to write a fair number of reports myself, but also in the course of business to read a vast quantity of reports by other people; and it is much easier to find out the weak points of others to point a moral than to set a proper example oneself. The proper examination of and reporting on mines can never be covered by a set of rules, for in this work the personal equation plays an important part, and training, ability and even experience are all insufficient in many cases unless accompanied by the common sense and sound judgment necessary in all business transactions.

There is such a great variety of badness in mining reports that a little grouping of the cardinal sins will be useful. In speaking of mining reports generally, for the purpose of illustration, I intend to cover not only those made by mining engineers, but all those used in business, and so fairly subject to criticism, from that of the learned professor of other sciences who is dragged from the seclusion of his study and put underground, to be made miserable with candle grease, down to that of the practical miner, who, having beaten a drill for a certain number of years, is prepared to dogmatize also on facts, figures, theories and conclusions.

Among the old friends we meet in numberless reports, and which seem to need a little protection against excessive wear and tear, the following will be considered:

1. The true fissure vein.
2. Increasing width in depth.
3. Increasing richness as depth is attained.
4. Junction of veins.
5. Ore in sight.
6. Proximity to a rich mine.
7. Failure from mismanagement.

Now, heaven forbid that I should be held as speaking disrespectfully of any one of these things, each estimable in itself. My remarks are pointed only against their indiscriminate use, and particularly against their public use as catch-penny phrases in a way to imply more than they actually mean.

The True Fissure Vein.—There has been more joy over this one term than over anything else in the history of mining. The investing public has become intoxicated with the exuberance of its descriptiveness. The practical miner has grasped its effectiveness, and the first ring of his pick on an outcrop satisfies him he has got the genuine article with tap roots in the Antipodes. What is a true fissure vein? It is supposed to be a fissure in the country rock filled with veinstone, which may be expected to go down to a considerable depth. The veinstone itself sometimes carries pay ore. This does not seem much to base any elaborate calculations on; and not only is it insufficient, but experience all over the world has shown that some of the most valuable ore deposits are not found in fissure veins at all.

Even as far as mere depth is concerned, it is by no means yet established that true fissure veins go any deeper into the earth's crust than bedded deposits, contact or pipe veins; and it would be of no consequence if they did go deeper, since they cannot be followed. I have read a report of a geological expert who expressed himself as ready to stake his reputation that a certain vein would go down and carry its value to at least 1000 feet. Properly used, the term "true fissure" is usefully descriptive, but where used as an incantation to call up visions of wealth to an unlimited depth it needs suppressing.

Increasing Width in Depth.—It is naturally gratifying to the owner of a mine to see his vein increasing in width as he goes down on it. It also looks well as described in a report, and must naturally be mentioned when it occurs; but in some reports the implication arises that it is a vital point and to be calculated on as continuing. If a vein went on increasing in width it would very soon attain enormous dimensions; and if it outcropped in a country blessed with the law of the apex, its lucky owner would have a good claim to a very large proportion of the earth when he got down a few miles. It may pretty safely be assumed that the increase in width will not continue, and when it stops it is very likely to be succeeded by a corresponding decrease, so as to keep up the usual average of things. When, say, a fifty-feet shaft sunk on a vein shows an increase in thickness from one foot at surface to six feet at the bottom, there is nothing to show that in continuing to sink the vein may not gradually or rapidly pinch again to its size at surface, or even much less. If any calculations were justifiable at all in such a case, general experience would certainly lead one to expect such decrease. The only positive conclusion would be that the vein is irregular in width. It looks nicer and more definite in a report to say simply "the veiu is steadily increasing in width as sunk on," than to state that "the width of the vein is variable, running from one foot to six feet, and therefore until further opened in length and depth its average cannot be safely calculated on." The one statement is as true as the other, but the effect of the two in reading is not the same.

Increase in Richness.—There is a touching confidence in the belief of many practical miners that veins get richer as they go down. Experience and disappointment often fail to shake this comfortable belief. The remarks made as to irregularity in width apply equally to increase in richness with depth. Most practical men are able to cite a great many more examples of rich mines becoming poorer with depth than the reverse. I remember being struck with the inconsistency and persistency of the belief in depth in various camps of the Rocky mountains. Up to the highest ranges, say 12,000 feet above sea level, there are mines which need sinking on to prove their real value; and 7000 feet below them in the foothills are mines equally needing depth. Probably the thought at the bottom of this belief rests, like some of the attractiveness of the true fissure veins, in the old idea of a central seething mass of precious metals, and in the forcing up of a molten vein-filling. This faith in the saving grace of depth and of true fissure veins, in the face of facts, can only be explained by the definition of faith as given by the little girl; viz., "believing what you know is not true." The hankering for depth has its justification, of course, in the necessity for sinking usually to get any developments, but where access is obtainable to the foot of a mountain through which a vein runs, the same men who claim a special efficacy for depth in other cases will point to the vast advantages of having the ground above one to be opened by adits. The facts of experience show that when a vein is rich at the surface, a hope that it may continue is a more proper attitude than a belief that it will get richer in depth; and when it is poor on surface, any change in sinking would be for the better. Naturally these remarks do not apply to cases of known ore shoots of established directions.

Junction of Veins.—Striking cases of enrichment of veins at their junctions occur; but, as many examples of junction without richness also exist, it does not do to attach too much importance to the results to be expected. In some reports the future junction of two veins is often itself assumed on insufficient data, and the consequences are calculated on with a certainty which is still less to be justified. In this, as in other matters, Nature seems to have a rooted objection to fixed laws of clear and simple expression, and prefers them with so many "buts" and "ifs" that she is still practically free to do as she pleases.

Ore in Sight.—Under this head is included matter which is of the very greatest importance, and which requires the very best work of an engineer. The estimation of ore in sight in an opened mine often involves the consideration of so many points, and is so largely a matter of good judgment, that one may expect some discrepancy in the reports of different engineers. There is nothing in which such vast discrepancies do exist, in fact, as in regard to this. Two good engineers will vary in their estimates, and when it comes to inexperienced men, or to so-called practical men who have no reverence for the written word, the term "ore in sight" becomes a theme for the exercise of the highest flights of imagination, and the airing of a little rudimentary mathematics. In the common mining report we are all acquainted with, it is not unusual to see the length of the chain multiplied by a cheerfully assumed average width of vein, then by 500 or 1000 feet for depth, and a tonnage deduced which reminds one of the figures used for astronomical purposes. Sometimes, to inspire extra confidence, the expert generally knocks off 25 or 50 per cent, and feels he has then done his duty, whatever happens. The character and ability of a man can sometimes be closely estimated from the way he figures up ore in sight after giving the dimension bearing on it, and it often suffices to look at this calculation in order to determine a report to be not only quite unreliable as to conclusions, but equally irresponsible as to data.

In connection with estimation of ore in sight, the system of sampling employed is worth mentioning here. In some reports the expert writes of taking samples "at random." When a man says he has picked some samples from a dump "at random," and they assay well, he implies that such ore is plentiful on the dump, and that he did not purposely select it from its appearance. What his statement actually means is, that on an important matter he was willing to trust to luck as to whether he hit poor or rich ore, or whether he was getting just what had been previously placed for him to get. Luck is a very necessary thing in mining, but it should not enter into sampling. If the sample is a random one its value proves nothing. Some people seem to think this method of sampling is important evidence of an impartial mind, and that shutting the eyes is the best security against the frailty of human nature, which would otherwise lead a poor creature to pick out the richest looking ore he can find.

Another little weakness to be remarked in some reports is the willingness to make a liberal discount off the expert's own figures. The writer concludes, for instance, from his samples—perhaps taken at random—that a gold vein will average two ounces of gold to the ton, but, to be on the safe side, generously offers to take it at one ounce, and then with a light heart goes into calculations by day, and month, and year. If a man knocks off 50 to 100 per cent from his supposed reliable figures to be safe, it always occurs to me that the one who reads his report may feel tempted to lop off another equal percentage to be still safer.

I do not wish to be understood as condemning the very proper allowance which a careful man will make for the difference between results of milling large quantities of ore, and the assays of samples from the clean veinstone, owing to intrusions of waste rock and breaking down of country rock in mining when everything practically goes to the mill without sorting. The system here objected to is that of doing careless sampling, and then making a heavy deduction to give the appearance of being on the safe side.

Unless a vein is very regular in value, the careless averaging of assays by mere numbers, without reference to the relative quantity of ore represented by each sample, leads to most misleading conclusions.

Proximity of a Rich Mine.—There have been plenty of illustrations lately published in prospectuses of the great value the public places on a property which is near a well-known mine; yet every one who knows anything of mining must be aware that mere proximity to a paying mine gives no assurance of similar success. The extraordinary continuity of the paying reefs at the Randt—an occurrence not applicable to quartz mining in any part of the world—seems to have caused a forgetfulness of the past costly experience in reckless mining investments by English companies. In Western Australia, although all evidence seems to point to some very valuable properties, it will be a truly extraordinary thing if there is not a great deal of disappointment resulting from the loose and unconfirmed reports lately published in some prospectuses, and which reports are illustrations of most of the defects mentioned in this paper. Some of these reports are absolutely nothing but a statement that the claim examined is on the same reef as, or near to, another property which is popularly supposed to be exceedingly valuable, and that rich ore has been found on the claim. Not a single attempt is made to describe the proportion of rich ore to poor rock; in fact, there is no mention of anything poor, so that the inexperienced are left to suppose that the full width of veiu is rich ore.

In quartz mining it sometimes happens that a series of paying mines are found at intervals along a single vein. Occasionally the intervals between pay shoots are long, so that a good mine may be immediately surrounded by poor ones. In other districts one single good mine on a vein is all that is ever developed. The only actual advantage of the proximity of a good mine is the evidence it affords of there being payable ore in the district, or on a certain reef. Like other indications, it is of service only when used with discretion, but as an unqualified argument of the value of a neighboring claim it is most dangerous.

Failure from Mismanagement.—That bad management may spoil a good mine is so self-evident a proposition that no one will misunderstand a few remarks against the improper or thoughtless use of this excuse in a report as an explanation of previous failure in a poor mine. A well-known Californian mining man, when asked to take charge of a mine which had failed to pay—as it was explained—from mismanagement, answered that he did not want anything to do with a mine which would not stand bad management. This is a remark which contains much matter for reflection, and embodies the opinion of most practical men. In reports the statement is sometimes loosely made that milling results in the past cannot be relied on, owing to primitive machinery or processes hitherto employed. This argument has often been advanced on Mexican mines by experts who have not had time to find out that native methods of working often give better results than the rapid working of the most modern machinery. With free gold ore it often happens that very simple and crude machinery will give quite fair results; an arrastra, for instance, will beat a stamp mill. In calculating on such past work by the owners of a property, it must not be overlooked that, even if they did fail somewhat in theoretical extraction, they probably selected better than the average grade of ore to begin with. Therefore, when average assays indicate higher milling value in a report than past returns, it is natural to look with suspicion on the sampling, unless some good explanation, better than the supposed blundering of former management, is given. Such explanation is, of course, simple enough when the process previously used is evidently not adapted to the ore; but it must be shown, not assumed because the machinery seemed to be crude.

The difference between the method of an experienced, responsible engineer and that of the inexperi-

*Paper read on Dec. 19, 1894, at the meeting of the Institute of Mining and Metallurgy.

enced or reckless expert, is that the former takes as little for granted as possible, aud will not prophesy unless he knows, while the latter gives the reius to his imaginatiou. We all remember the luxuriant crop of reports in the early days of South African gold mining, written by authorities whose previous mining experience had been coufiued to the costeaning of a potato patch, or to exploratory operations on their neighbors' bank accouuts. Some of these sanguine gentlemen, who took every surface showing gold as sure evidence of vast wealth below, scored some brilliant successes on the Randt, although their ounces became pennyweights in working; but when they extended the system to the regular ruu of gold veins in other parts of the country they met the usual slap in the face which nature keeps for rash prophets. The careful man is of necessity at times discredited in the opinion of those who misunderstand his responsibilities, by reason of his refusal to become excited by a good surface show, which his experieuce tells him is no safe guide as to depth; while the reckless and inexperieuced will freely call on their imaginations. There are cases of this description iu which, however rich a miue may afterward prove, it is more creditable to have been cautious than to have been sanguine in the early stages. If it would not be held as rather unduly exalting the profession, I should quote in this connection, "Fools rush in where augels fear to tread."

After all these remarks as to what mining reports ought not to be, it is perhaps permissible to say a few words on what they ought to be, but with the apology to our inexperienced members already referred to in introducing this paper.

A report need not be long winded to justify the fee paid for it, but should be so full in actual description as to enable a reader inexperienced in mining to draw his own conclusion from the facts given, without having to trust entirely to the deductious of the writer. Where a fee is paid for a simple expression of opinion or specific advice, there is uo need of a report, in the seuse of the word as we are now considering it. The important details to be set forth clearly are those relating to position, and facility of access to the property; local conditions as to fuel and water, and timber supply; extent and form of openings; variations in thickness of deposit; character and value, and form of occurrence of ore. It is important in giving a clear idea of the property that the distribution of the payable ore in the deposit should be described. It makes a great difference sometimes in the conclusions to be drawn, whether the value consists in rich ore occurring iu a barren vein mass, or in high-grade ore scattered through a low-grade deposit, or in a uniform value throughout the rock. On account of the necessity for this description, it is uot always sufficient to state that an average width of vein contaius an average of so much value per ton, as this may be in the nature of a conclusion, not of a fact, and so may need to be justified by detailed facts of the report. The extent and character of dump piles at a worked mine often afford valuable confirmatory evidence as to the character and value of the property. I have seen reports in which piles of rich ore were stated to be ou haud at the mine in certain quantity aud value; but on figuring out the experts own statements as to width of pay ore and extent of openings, it was clear the hole in the grouud could uever hold the ore said to have come out of it. The configuration of stopes in a worked mine often gives very suggestive ideas as to the run of pay ore, and as to the probable character of ground still standing.

Geology and mineralogy should naturally be used with discretion, but only for purposes actually bearing ou the description and conclusions to be drawn, not for mere paddiug, nor for the airing of theories better treated in a purely scientific paper. I have seen a report which started with the nebular hypothesis, and traced the progress of the earth from its pulpy state right down through its various stages to oxidation of the outcrop of a particular veiu in the year of grace in which the report was written. These details were so full that there was no room left for anything but a brief treatment of the merely commercial question of the value of the mine.

Examinations naturally differ greatly in the nature of the calls they make ou the expert. In a district with which he is well acquainted there are often certain simple facts which enable him rapidly and safely to arrive at his conclusions; in other cases it is often a matter of hard and conscientious work, however clever or experienced the engineer may be, and any scamping of this work will imply unreliableness.

Finally, au experienced man in making a report will have au open mind for possible uew forms of orc occurrence, while refraiuing from prophesy about things not iu sight. Events may work against the most careful and experienced man by unforeseen increases or decreases in value ou opening new ground; but as mine examination is au art and not an exact science, it is by average results that au engineer must be judged. A mining eugineer has ouly ordinary eyes, aud so, as Sam Weller says, his "wision is limited"; if he had "a pair o' patent double-million magnifyiug gas microscopes of hextra power" he might look into the earth a little farther.

(To be continued.)

Mr. Badlam Objects.

Quite a flurry has been caused among the directors of the Bullion–Beck & Champion Mining Company during the past few days by the presence in the city of Alexander Badlam of San Francisco, who represents a minority of the stockholders of the company.

Mr. Badlam arrived in the city last Monday in response to a telegram, and reached a meeting of the board of directors in time to hear a resolution read which proposed the purchase of the Caroline mine from John Beck by the Bullion–Beck Company for the sum of $175,000. After listeuing to the reading of the resolution, Mr. Badlam spoke right out in meeting and vigorously opposed its adoption on the ground that the ore in the Caroline was already the property of the Bullion–Beck Company, and no action was taken upon the resolution.

On January 2d Mr. Badlam addressed the following communication to each of the directors of the company:

DEAR SIR: You are one of the hoard of directors of the Bullion–Beck & Champion Mining Company, and the subject of huying the Caroline mine from John Beck is now hefore the board. I am a stockholder in the company, holding a considerahle hlock of shares, and I represent other large stockholders. I warn you against concurring in the purchase. The company owns now all the ore under the surface of the Caroline mining claim, and the Caroline is not worth a cent. If the company purchases the Caroline with your vote, myself and associates will look to you personally, and hold you responsihle for the loss and damage to the stockholders of the Bullion–Beck & Champion Mining Company. ALEXANDER BADLAM.

Yesterday Mr. Badlam and Mr. Beck held a consultation, and finally agreed to submit their differeuces to a board of three arbitrators; but after Mr. Badlam had uamed W. H. Dickson as his representative, Mr. Beck refused to arbitrate, and the gentlemen parted.

Mr. Badlam returned to San Francisco last night. —Salt Lake Tribune, January 3d.

Coal Importations.

The following tables sbow the sources of California's coal importations for the past four years:

	1891, Tons.	1892, Tons.	1893, Tons.	1894, Tons.

Scientific Progress.

Soldering of Aluminum and the Production of the Metal.

It has been said that the great objection to the widespread use of aluminum as a substitute for other metals now in daily use is that it cannot be effectually soldered. True, so far, there has been some difficulty in finding a suitable solder; but, as was to be expected, when the metal came more and more into use and got better known, as it has done during the last two or three years, many inventors have devoted their time and attention to the solution of this problem. Ten patents for soldering have been granted. Two or three of these processes have passed the experimental stage and are now being used.

One of the difficulties found in soldering the metal has been that the quality of the solder used could only be ascertained after a certain period had elapsed, so that, while some of the solders seemed to have answered very well at the time of application, after a few weeks or a few months' time the pieces which had been joined could easily be broken again.

Aluminum is easily oxidized, and as soon as it is exposed to the air, however brightly polished it may be, it instantly becomes covered with a thin film of oxide of aluminum. This peculiarity is a decided drawback in soldering, although in other uses it constitutes one of its best qualities, the thin film preventing the metal from becoming further oxidized, and thus keeping it from turning black as with silver, copper and other similar metals.

The secret is to see that the pieces of aluminum to be soldered are entirely free from any oxide, otherwise it is said to be utterly impossible to join them strongly together; in fact, one might as well, it is explained, try to join two pieces of rusty iron together.

The process for soldering aluminum, recently invented by M. Ludwig Oliven, seems to have overcome this difficulty, and exhibits recently shown have stood requisite tests. The invention consists not only of the new solder, which is an alloy of several metals, but also of the combination of this solder with a suitable patent furnace for keeping the metal at the right temperature at which the operation should take place, and also with the arrangement of brushes and other tools, with which the surfaces may be scraped and cleaned so as to get the solder well into the metal. Small pieces can be soldered by means of the blowpipe, but when large pieces of the metal have to be treated, and especially when the solder has to be of an exceedingly good quality, it is most advantageous to make use of the special furnace invented for this purpose. The entire process is simple. Any workman by this process will be able to solder any pieces of aluminum just as simply as he can any other metal. Pieces joined together by this process have been submitted to crucial tests and have proved more difficult to tear apart than brass united with tin solder.

The fact of being able to solder aluminum by a simple and cheap process should enormously extend the uses to which the metal may be applied.

The annual output of aluminum has increased from 50 tons in 1890 to about 2500 tons in the last year. The price of the metal has, at the same time, diminished from $15 per pound in 1889 to about 40 cents per pound at the present time. As aluminum weighs, bulk per bulk, only one-third of the other metals now in use, the least mentioned price corresponds favorably by comparison.

All the aluminum sold in the market is manufactured by electricity. The largest factory in the world engaged in the manufacture of aluminum is one at the Falls of the Rhine, at Neuhausen, Switzerland, which is capable of producing 1000 tons per annum. The second largest factory is in the south of France, which uses water power from the Alps, with an annual output of 600 tons.

Detecting Dynamiters.

Chemistry is offering a means to oblige would-be dynamiters to betray themselves should they try to carry about hand grenades and cartridges. It is to mix dynamite with certain salts that give out a stench, and plunge cartridges into a solution of these chemicals. This fœtid smell thus caused is not to be got rid of, and is communicable. A person carrying this infernal machine, or who had carried or handled one, unless with leather gloves which had been taken off with great care, would be at once detected by the odor.

In a communication to the mining society of Nova Scotia, C. E. Willis says the metamorphic rocks and serpentines of Quebec dip under the Gulf of St. Lawrence to re-appear on the western coast to Newfoundland, and extend probably across the island. The district, situated at and near the eastern coast of Port-au-Port Bay, near the southern boundary of the serpentine rock, is seamed in many places with asbestos, and contains veins of copper and specular iron. Only surface work has been done so far, but the asbestos fiber is of good quality, up to 2½ inches long, and practically identical with the Canadian product.

A SCHEME has been proposed to reduce the friction of salt water against the sides of a steamer, which, it is claimed, will increase the speed forty per cent. It is to force air through the vessel's plates and thereby form a narrow space between the iron and water.

Horseshoes of Cast Steel.

Every now and then one hears of an attempt to make a horseshoe by casting instead of forging it. A Chicago firm produced a lot of such shoes a year or two ago, and the experiment has been tried by others. A few weeks ago, in Glasgow, there was a public exhibition of a new attempt in this direction. A mould of steel was used, and this was provided with such mechanism that, immediately after the shoe is cast the matrix may be opened, whereupon one lever causes two cutters to remove the surplus metal, and another operates punches which make the holes. The steel used was a Bessemer, made by the Walrand-Legenisel process, whereby great heat and fluidity is secured by putting a little ferro-silicon into the converter just as the blow is finished. It does not appear from the story at hand whether or not toe and heel calks are formed on the castings, but one is left to infer that the blanks are in substantially the same unfinished condition as the forged shoes now so extensively used in this country. The latter require not only the addition of the "clip" and calks, but also more or less shaping at the hands of the shoer, to fit the horse; and it is difficult to see how such work can be done on a casting, owing to its brittleness.

It is now something like forty or fifty years since machine-made shoes were introduced in the United States. These met with opposition from blacksmiths at first, but they have grown in popularity until now the great majority of working-horses out in Eastern rural districts are thus shod. In cities, too, they are in constantly increasing use. Street-car companies which still rely on horse power, use machine-made shoes. In many cases a better quality of iron is employed in manufacturing these shoes than is sold to the blacksmith for the hand-made article. Many owners of private carriages imagine that the latter style of shoe is preferable; but within five years a light machine-made shoe of Bessemer steel has come into the market, which seems to be well adapted for this class of custom. There is nothing like it in Europe. The machine-made shoes in general have not been appreciated so fully and promptly there as on this side. Of course, the great majority—say ninety-five per cent—of them are made of iron, and not of steel; but veterans in the trade scoff at the idea of casting the metal, whether it be one or the other, for the reason already given.

Commercial Products Obtained from Sharks.

Sharks, says a writer in the *Revue Scientifique*, furnish quite a number of valuable products. Thus, the liver of the shark contains an oil of a beautiful color, that never becomes turbid, and that possesses medicinal qualities equal to those of cod liver oil. The skin, after being dried takes the polish and hardness of mother of pearl. It is marbled, and bears a resemblance to fossil coral. It is used by jewelers for the manufacture of fancy objects, by binders for making shagreen, and by cabinet makers for polishing wood. The fins are highly prized by the Chinese, who pickle them and serve them at the end of a dinner as a most delicate *hors d'œuvre*. A ton of fins usually brings (at Sydney) $140. The Europeans, who do not yet appreciate the fins of the shark as a food product, are content to convert them into fish glue, which competes with the sturgeon glue prepared in Russia. This glue is employed for clarifying beer, wine, and other liquors. It is used also for the preparation of English taffetas, as a re-agent in chemistry, etc. The teeth of the shark are used by the inhabitants of the Ellis islands for the manufacture of weapons of war. As for the flesh of the shark, that, despite its oily taste, is eaten in certain countries. It is employed also, along with the bones, in the preparation of a fertilizer. The Icelanders, who do a large business in shark's oil, send out annually a fleet of of a hundred vessels for the capture of the fish.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Mendocino.

Press: About forty-five years ago a Mexican discovered a gold-hearing ledge near Ukiah, from which in a short time he succeeded in extracting a fortune, variously estimated at from $40,000 to $80,000. The rock was of such a character that even by the primitive methods then in use the gold was extracted in a comparatively brief period. Some weeks ago C. H. Stout, while prospecting the low ranges east of town, discovered evidences of former mining. At or near the stopes worked by these prehistoric searchers for the yellow metal he found rock that gives evidence of richness. He has located 600 feet of mineral land in the vicinity of his discovery and is sanguine over his prospects. Mr. Mathias, the expert of the State Mining Bureau, stated on a recent visit to this county that, according to his opinion, there were excellent prospects in Mendocino for the discovery of rich ore helts, and said that as yet the county had not been prospected. This is doubtless true. Expert miners have rarely visited this county, and it is yet comparatively a virgin field for the expert prospector.

Nevada.

WEST HARMONY MINE.—The West Harmony drift mine near Nevada City has again started. Work was discontinued some time since on account of water. About forty men will he employed at the mine from this time forward.

Placer.

HIDDEN TREASURE.—*Sentinel:* The Hidden Treasure Company at Sunny South, operate their drift mine on the most extensive scale of any gravel property in the United States. The company has just closed one of the most successful and profitable year's work in the history of this famous gold mine. During the past twelve months they have breasted and worked an area of 260,000 square feet of channel, which has produced 110,000 car loads of pay gravel.

Last fall a new trail was built from the old works at Sunny South to the month of their newly acquired Dam tunnel, a distance of about two miles. A force of five men are at present engaged extending the tunnel.

During the past year the average number of men employed has been 180. The amount of money disbursed by the company for labor and material has been a trifle over $101,000.

The tailings in Blacksmith Canyon, which came from the sluices of the Hidden Treasure mine at Sunny South, will probably be sold some time during the coming month. They have not been worked for about three years. The Chinese usually purchase them. They sell for many thousand dollars.

After being worked, the tailings pass into El Dorado Canyon, where they are worked over and over by the Chinese who have claims located in the canyons.

OPHIR.—*Herald:* At the Gold Blossom mine the miners were laid off December 24th, on account of the water being too high at the lower level. Work was resumed, but most of the men had to quit again forty-eight hours after, because of the breakage of a valve on the steam pump. The milling process at this mine will soon be complete, and everything in running order. Sinking has been resumed in the west drift at the 200-foot level. A large quantity of ore has been taken out, and it promises to be good. At present there are about twenty-four miners, or, including outside laborers, thirty-five men in all, employed at this mine.

At Gold Blossom No. 2 the stamp mill is running and a force of men are at work in the mine.

The Boulder mine is making preparations for a new start. Mr. Brown is putting in some concentrators, and when these are finished operations will commence in the mine.

San Bernardino.

San Bernardino *Sun:* The new year is likely to be marked with renewed energy in mining in San Bernardino mountains. The persons who own stock in the Rose mine are to be congratulated on a Christmas present of a substantial nature. A rich strike at the depth of 425 feet has just been made, probably the richest strike yet made, and certainly the most important one. The ore has been struck in a good solid formation, which means permanency. The Rose can now he called a mine, not a prospect. The striking of this ore at this depth is of the greatest importance to the mining industry of this county, and especially to the San Bernardino range. There has been a prevailing opinion that paying ore bodies did not continue to any great depth in this county. This will prove to the doubting Thomases that the greater the depth the richer the ore becomes.

Shasta.

SALE OF THE TELLURIUM.—The Tellurium gold and silver mine, three miles from Redding is reported sold to a San Francisco and Eastern syndicate for $300,000. The property was discovered by Peter Scherer some years ago, and he labored and struggled, spent every dollar he ever possessed and borrowed more to open and strike the main ledge. Finally he formed a joint stock company, issuing shares of the stock, which he placed on the market in this city and elsewhere.

Tuolumne.

Independent: J. H. Beal with D. R. Oliver, has located a quartz mine at Hog Mountain, six miles southeast of Sonora, the Tuolumne river cutting through it. The lode has been located on both sides. The croppings show ore that will yield from $6 to $8 per ton; plenty of water and timber at hand; will drive a tunnel right from the river bed. Mr. Beal has prospected, he says, over 8000 miles, and from Alaska to Peru also in Australia and Africa. He says that Tuolumne offers a better field for developing rich mines than any section he has ever visited. He says the hidden wealth of this county has never been dreamed of. Depth will prove this. He says: sink the Rawhide to 1800 feet, it will prove the richest mine in the world.

ARIZONA.

ON THE HASSAYAMPA.—*Journal-Miner:* J. A. Conlee has taken a twelve month's bond on the King Solomon group of mines, on the Hassayampa, eight in number, and two mill sites and a mill for $50,000. The mines are owned by Judge Abner Wade and others and as far as opened up look in fine condition. Mr. Conlee will put a force of men at work on the mine about February 1, and will push development work on the mine as well as the mill.

Needles *Eye:* An old prospector who has been examining the Wickenburg district says: "This is the hardest country I ever saw to prospect and no matter how good the man, he cannot go beyond the limits of his canteen. Water is scarce and in the mountains or on the desert men drink like fish. It is impossible to carry a supply sufficient to last any considerable leugth of time, and no matter how near the sturdy miner may he to the vein of glittering riches, when the canteen begins to fail he has played the limit. There are indications of gold everywhere, and Central Arizona will some day show many fine gold mines. The country has many surface symptoms, and the mineral in places is rather pockety."

IDAHO.

TO WORK IDAHO PLACERS.—The Blue Lakes Mining Company, consisting of Messrs. J. C. Conklin, president; J. E. Oglesby, vice-president; L. B. Gorbam, secretary; F. A. Virtue, treasurer; and C. J. Pence and J. B. Perine, of Salt Lake, will operate in Idaho, about twenty-five miles from Shosbone, to work 400 acres of placer mining ground. The company is capitalized at $125,000, with that number of shares. It bought the placer property in October last, and was engaged up to December 15th in erecting hydraulic and milling machinery. Since December 15th it has been experimenting with the plant, and is now prepared to announce that success has been met and that future prosperity is assured.

An entirely new milling process is involved in the mine. It is known as the Bard amalgamating machine. Full particulars of its method are not available at this writing, but it can he said that it employs a riffled copper plate, and uses quicksilver. The company has five of the machines in use, and has been able, with them, to save 95 per cent of the gold, while handling from 700 to 1,000 yards per day of dirt.

The hydraulic equipment of the mine includes about two miles of flume and ditch, with 1,000 feet of eight-inch pipe line. The pressure is 100 feet. Water is drawn from springs which have a flow of 3,000 inches.

Objection is taken by the company to stating the showing of the placers, on the ground that it is too high for general credence, though only so high as to cause the company to resolve to keep the mine in operation all winter.

THE LEASE SYSTEM.—Boise *Statesman:* Major William Hyndman, manager of the Philadelphia Mining Company's mines and smelter at Ketchum, says the lease system under which all of the company's mines are being worked is proving more advantageous to the company than when the mines were worked by the company, and the lessees are making money. Up to the time Major Hyndman took charge of the Philadelphia company's interests at Ketchum, the company had expended fully $1,500,000 without realizing a dollar of cash profit. This was due to exteusive investments. Major Hyndman saw that the continuation of that state of affairs would be suicidal and he determined to lease a number of the properties to the miners. The results have been very gratifying.

The lessees are now operating seven of the company's mines. They pay a stipulated royalty and, even at the present depressed price of silver and lead make fair wages, while Major Hyndman makes regular remittances to the company, representing a snug little sum each year in excess of Mayor Hyndman's salary and other expenses. Only the richest ore is shipped. Major Hyndman says he shipped 300 tons of concentrates for the lessees this year.

MINING LEGISLATION.—The *Busy Bee* of Albion, Idaho, reports a meeting of miners at that place at which a committee was appointed to prepare resolutions on the subject of mining legislation. The *Bee* says: "The principal feature of the discussion at the meeting was the easy, go-as-you-please law of location. Under the present and existing laws a man, or a number of men, can stake off and locate the whole country, no speculations, and can hold it a year and the fractional year in which the location is made, without doing a tap of work, and we are sure without producing or developing any appreciable advantage or good result to the country, but on the other hand with the marked and perceptible disadvantage of retarding any measure looking to a speedy development of our mineral area. The present laws only protect the speculator, with the result of keeping out persons who might otherwise come in and do something. In this direction the Colorado law is looked upon with much favor, and it is highly probable the resolutions committee will recommend some such law for our State. There, before a locator can even record a claim, he must sink a shaft on the ledge ten feet deep, representing an hundred dollars worth of work, and had we the same law here it would certainly work to a great advantage to the country.

THE 'FRISCO MINE.—At the 'Frisco mine where the mill was blown up during the strike of two years ago, the wrecked mill has been replaced by a large structure and capacity increased from 150 tons per day to 400. The mine employs altogether about 145 men, and is still worked by tunnels. The upper two have been stripped of ore and the present work is on tunnel No. 3 which is 300 feet below No. 1. The outcropping of the mine when first discovered were small. In tunnel No. 1 the vein showed three feet of good ore; tunnel No. 2 increased the vein to about six feet, and now in tunnel No. 3 it shows an average width of about sixteen feet, though in some cases it widens out to forty feet. The present tunnel was run in 1,052 feet before the vein was found. Along this they have drifted 800 feet. The mine is operated by water power entirely, having developed 150 horse power. Compressed air drills will be used in sinking the shaft. The ore is conducted out of the mine by mule trains, each train load being about fifty tons. The mill is running at full capacity and ships from 1,200 to 1,500 tons of concentrates every month. The mine will run all winter unless some emergency arrives to change the present arrangements.

MONTANA.

The citizens of Granite county are endeavoring to secure the erection of a smelter in the vicinity of Philipsburg to treat the ore of mining camps in Missoula, Deer Lodge and Granite counties.

Several Bozeman citizens are interested in the coal fields on Trail creek, in southeastern Montana. It is reported that for many square miles the coal lies not to exceed three feet below the surface and that it is of high grade. All that is needed is railroad facilities for the development of this section.

It is almost impossible to sink a shaft or run a tunnel for any considerable distance on the mountain west of Main street in Marysville, says the *Mountaineer*, without encountering a pay shoot, and yet most of this land is open to location. A man with a few thousand dollars might here find a profitable investment and strike a bonanza.

The Marysville *Mountaineer* says that the Monitor mine, with Messrs. McKillican and Boyer Bros. proprietors, is showing up finely and that the new mill is kept steadily at work on rich ore. This is the property the Boston tenderfoot was afraid to purchase. He could have made $10,000 by purchasing the property and holding the same a few months.

The output of the placer mines owned by the La Crosse Bros. and Barrett on Cedar creek, in Missoula county, is said to have been $26,000 in gold dust.

The Harvey district, in the vicinity of Philipsburg, is attracting considerable attention. It is a gold hearing district, and some of the mines are reported very rich. Some of the quartz taken from the mines runs from $5 to $500 per ton.

J. E. Morse has sold the Midnight mine to A. V. Clark, representing St. Louis parties, says the Dillon *Examiner*. It is understood that work will begin at an early date and the mine be fully developed, and in all probability a mill will he built next spring. The price paid was $11,500.

The San Martina Mining Company, owning mines near Martina, in Missoula county, during the past year has constructed a five-stamp water power mill, built a hoarding house and made many other improvements. The mill was started up in October and has been running ever since.

MEXICO.

SONORA.—C. B. Serventi, of Altar has a property twelve miles from the coast: the water they use is brought twenty-one miles. The ore is packed on burros twenty-five miles to be worked. It is worked in steam arrastras, and pays to work it even under such disadvantages. It is a gold property, free milling and rich. The ore that is sorted and worked runs $200 to $300 to the ton. The average of the mine is at least $30.

Sinking has been done to a depth of 200 feet for water. The bottom of the well is as dry as an Arizona mesa as yet. The owners will not sink farther for water at present. Water is packed into camp in small kegs and brings one peso a keg.

The mine comprises two claims, one of 800 metres in length, the other of the regulation 600 metres. The mining laws of Mexico allow the discoverers of new districts an extra 200 metres for bringing out new fields. One of the two mines being the pioneer of the district it is larger than the regulation claim. The owner is now negotiating with San Francisco parties to sell the property. All arrangements were once made for the sale of the mines to Denver parties. That, however, was about the time of the late panic, and owing to that the sale fell through.

NEVADA.

ESMERALDA CO.—Walker Lake *Bulletin:* Col. W. J. Sutherland, Managing Direetor of the Holmes Company, arrived in Hawthorne Friday and took a special from here to Candelaria. On his return, Sunday, Mr Sutherland said that he was testing the ore and tailings of the Holmes mine with a view to working the same on a large scale by a new leaching process. Thos. Reed, the well-known mineralogist, is at present making tests, and on his report depends the action of the company. Mr. Sutherland said he thought work would begin within a month.

There are half a million tons of tailings at Belleville and Candelaria; and a plant will have to be built to do the work on a large scale. There are also large bodies of ore in the mine which will no doubt pay well if treated by the new process.

This is a gleam of light through the dark clouds that have overhung Candelaria since the big mines closed, and it is the earnest hope of everybody that the tests now being made will prove satisfactory.

The report published in the *Enterprise* that Mr. Sutherland is negotiating a sale of Ed Brown's mine at Silver Star is a fairy tale. He did not visit Star district, but he has arranged with Mr. Reid to go there and inspect the mines in his interest.

A GOLD MINE.—Mr. E. B. Coleman has recently acquired for an Eastern syndicate the property at the head of the Owyhee, about sixty miles north of Elko, consisting of some very rich free gold quartz veins. At a depth of thirty-five feet the veins have widened, but the average thickness thus far has been about three feet. A small vein of twelve inches has assayed as high as $1000. It will soon he determined whether the company shall erect only a small concentrating plant or put up a full reduction works. A force of men is now employed in developing the mine.

NEW MEXICO.

Record: R. B. Hunter of the Bucyrus Placer Company, operating in Merino valley, Colfax county, New Mexico, gives good reports of the past season's operations on the company's property which extends some six miles down Merino creek, near Elizabethtown. The working season, which begins about the first of April and runs to December 1st, is conducive of constant operation. Advantage of this fact was taken by the Bucyrus company during the season. A large Bucyrus amalgamator with a capacity of 1,000 yards daily has been used with such marked success that it is quite probable that another will he added this year. Mr. Hunter says that fully 95 per cent of the values were saved and there was absolutely no gold in the tailings. Mr. Hunter has mining interests in Central America and expects to operate on a profitable scale in that country next season. He anticipates a big year in gold mining for 1895 and says New Mexico will come to the front in a surprising manner.

OREGON.

AT WOLF CREEK.—According to reports brought in by one of the miners of Mount Reuben the chemical process for working refractory ores, which was being tested by Messrs. Beardsley and Wetherell on the Copper Stain mine on Mount Reuben, has proven a success. They have their three-feet pan in operation treating tailings. It is reported that as a result from less than forty-eight hours' run they cleaned up $600. The Star Mining Company will soon have their machinery in operation on the Star mine on Grave creek.

UTAH.

GOLD COIN DEVELOPMENT.—*Tribune:* The owners of the Gold Coin group of mines in the Mercur district have let a contract for one hundred feet of crosscut tunnel to open up their property. The work is to be begun at once and pushed to completion as rapidly as possible. As soon as the vein is encountered, general development work, looking to the ultimate erection of a cyanide mill, will be begun. The owners of the property are Messrs. H. T. Bragden, Quincy Smythe, Carr and other Denver parties.

WASHINGTON.

The Cedar Canyon mines, situated in the mountain regions of Steveus county, and on the slope of the range which reaches down into Spriug valley, are attracting attention. A Mr. Hall, who was the discoverer, has charge of the development and work on the mines, and the recent shipment of ore from the mines to Davenport has caused considerable comment to be made as to the richness of the district. The ore is of a carbonate nature, and runs to the value of about $500 per ton. There is about four feet of ledge, and the mine is very easily worked, and is also accessible to wagon transportation. The ore has to be hauled a distance of about forty miles then shipped to Tacoma for treatment.

The Old Dominion mine, near Colville, which has been working steadily on development work for the past six months, will make some very radical changes at an early date. It is the purpose of the management to put an additional force of men on the property for the purpose of extracting ore and to start up the concentrating works as soon as the whether will permit. Several properties surrounding the Old Dominion that have been bought up by the company will make liberal contributions of ore to the concentrating works when they start up.

It Does.

"Does Electricity Kill?" is the caption of an article going the rounds of the press. Sometimes.

TACOMA, Wash., Jan. 5.—Two thousand volts of electricity passed through Peter Peterson, day electrician at the city light station, this morning, instantly killing him. In making changes on the switchboard he grasped two plugs at the same time, his thumbs touching them too far up and on the non-insulated portion. There was a flash and he fell back dead. He had been in the employ of the company six years. His death is attributed to carelessness.

THE 999, on the N. Y. Central, is still the queen of all locomotives. Her run of 436½ miles in 425¾ minutes stands as a world's record, and her mile in thirty-two seconds has never been equaled in this or foreign countries. But it is more than probable that within the next few months the New York Central officials will order one of these records broken by another engine, and will then give the 999 an opportunity to enter into the record-breaking business again.

Coast Industrial Notes.

—E. Coleman has been elected president of the Pacific Rolling Mills, vice J. G. Fair deceased.

—Edward A Rix has been granted patents for his Phœnix drill in all the Australian colonies.

—An assessement of seven dollars per share has been levied on the capital stock of the San Francisco Tool Co.

—The Gila dam and reservoir, the "Wolfley ditch," in Arizona, has been bought by Charles Crowley of Los Angeles for $500,000.

—The Vancouver, B. C., miners will continue to work at the present low wages six months longer, the coal market being rated "gloomy and uncertain."

—H. D. Morris has lately moved into commodious quarters at 143-145 First street, and is furnishing considerable machinery to mining companies in Sierra and Amador counties.

—John McNamara has sued the city of Seattle for $15,000 for infringement of patent on a mining machine used in tunneling. The city denies that the machine in use is the same as the one patented by McNamara.

—Water from the Bull Run river was turned into the mains of Portland, Or., last week. The water is brought nearly forty miles from the Bull Run river, a mountain stream rising in the Cascades near Mount Hood. The plant cost the city over $2,000,000.

—The Point Defiance Railway has been sold at Tacoma to S. Z. Mitchell of Portland for $82,000, subject to several mortgages, aggregating over $200,000. The principal holders of the mortgages are C. S. Hinchman of Philadelphia and J. C. Lewis.

—The gas plant and the Commercial electric light plant, one owned and the other controlled by the Tacoma Light and Water Company, have been transferred to Seymour, Barto & Co., C. B. Hurley, and some eastern men who make a specialty of the gas business.

—G. A. Sachas, of Eugene, Or., who is the patentee of a hammerless shotgun, has established a shotgun factory in that city, which, the *Guard* says, is the only complete establishment of the kind west of the Mississippi river. He will employ ten men, and expects to make about fifty guns a week.

—The Sierra Valleys Railway Company has incorporated to construct and operate railroads in Washoe county, Nev., and in the counties of Sierra, Lassen and Plumas, Cal. The estimated length of the road is 100 miles. The directors are J. M. Platt, J. Elder, J. Flitlie, F. F. Ryer and W. S. Kittle. Capital stock $1,500,000.

—The Tillamook Electric Railway, Power and Light Co., of Tillamook, Or., has filed articles of incorporation; its object being to operate an electric railway from a point on the line of the Oregon Central railroad in Yamhill county at or near North Yamhill station, westerly, following the course of the North Yamhill river, the Nestucca, and the Tillamook rivers to the shore of Netarts bay in Tillamook county.

—Charles England, of Kelso, Wash., who is running a logging camp near Olequa, has a long chute, just one mile long, and when a log is placed in it at the top of the mountain, it reaches the bottom, plunging into the Olequa creek, in just fourteen seconds. The chute is a perfect one, as there never has been a case where one jumped the chute. The water at the mouth of the chute is of sufficient depth that the logs are not injured in striking the bottom of the stream.

—The new Sierra Valley railroad, which has been completed for a distance of twenty-three miles and is projected to cross the Sierras through Beckwith Pass, has been mortgaged to the Southern Pacific. Nevada papers think that the fact that the Southern Pacific is aiding the project indicates that corporation has secured control of the property, with the probable intention of abandoning the Central Pacific line across the Heaness Pass route during the winter season, thus avoiding blockades and the heavy cost of maintaining the long line of sheds across the snow belt on that route.

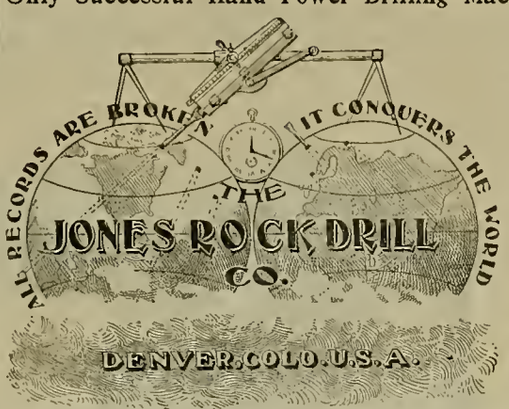
—The Southern Pacific Co. is figuring on supplanting its steam local service in Oakland, Alameda, Berkeley, etc., with electricity as a motive power. A year ago a contract was made out with a large Eastern company to put in the electric plant to run the local service. The papers were all ready to be signed when the reported invention of a German who had perfected a new and much more attractive system of electric motive power caused a delay. An agent was sent on to Germany to investigate the subject and to look into other systems in operation in Europe. Arrangements are now in progress for putting in a system of electric power, wherein the current or power is supplied from a slot between the rails, and overhead trolley wires will not be used. The new system will not only run for feeding the ferries, but for a street service as well. The cars will be somewhat larger than those running on the San Leandro line, and they will be run with two or three in a train. The ferry service will then be extended to Haywards and possibly extended to San Pablo. Electricity is a much cheaper and more expeditious method for short hauls such as are involved in the local service, than are the heavy steam trains. The company is anxious to obtain the latest inventions before making a change.

In Our Lap=

WELDED PIPE (MATHESON JOINT, for which we are agents) we are supplying an article of known excellence. A large line always in stock. We also make all kinds and sizes of SHEET IRON and SHEET STEEL riveted WATER PIPE for hydraulic mining, irrigation and other purposes. We want business—at least the way we make our pipe, the way we sell it and the way we treat customers would make you think so. Quotations and information furnished promptly.

RISDON IRON WORKS, S. E. HOWARD AND BEALE STS., SAN FRANCISCO

THE JONES ROCK DRILL
IS THE
Only Successful Hand Power Drilling Machine Ever Invented.



It is strong, durable, reliable, simple, compact, light, easily handled and operated by one man, and will reduce the cost of rock drilling at least Fifty per cent.

Our handsomely illustrated pocket catalogue fully explains the features and workings of the drill. It should be in the hands of every mine owner, leaser, contractor and prospector in the West. *Sent free on application.*

If you are interested in Rock Drilling Correspond with us.

WE CAN SAVE YOU MONEY.

FRANK T. SUTHERLAND, M'g'r Pacific Coast Agency.
Office and Warerooms: 9 FREMONT St., San Francisco, Cal.
Or, Address the Company at its Denver Office.

Blasdel Improved Concentrating Belt.

We keep in stock belts suitable for the Frue, Triumph, Johnston and Tullock machines, and make all lengths and widths to order.

Practical mill men must see at a glance the advantage of our belts over any other. First, the flanges stand at an acute angle toward the center, therefore readily conform to the change of direction while passing over the end rollers. Thus the vexation and loss occasioned by the frequent breaking of the flanges, as is the case with the old style, is practically overcome.

Again, in the surface of the belt transversely two feet apart, there is a space of one inch, containing twenty riffles 1-32 of an inch in depth. This tends to equalize the pulp and prevents it from banking on the edges, or forming channels. This riffle saves fine sulphurets and quicksilver that would escape with the tailings from a belt with an entirely smooth surface.

Electrical Progress.

The Great Dynamos at Niagara.

Three of the euormous dynamos with which the Niagara Falls Power Company is to develop electricity have been completed, and are now being set up. The initial stage in the practical operation of that wonderful scheme, therefore, is elose at hand. In several respects besides their uueqnalled capacity — 5000-horse power each — these generators are unnsnal, not to say original. And while it is possible that a few months of service may reveal ways in which improvement can be made, these machines represeut the very latest and best ideas in electrical engineering. The caual which is to bring water to this great plant was long ago completed, as was also the tunnel (7000 feet in leugth) that serves as a tailrace. The wheelpit was ready last summer, and during the last four months the turbiues and penstocks have been put in place. Everything is in readiness, therefore, for the crowning task of installing the machinery here described.

Most dynamos are driven by a horizontal shaft. Those at Niagara have vertical shafts, reachiug down to the water wheels, 136 feet below. Although each wheel weighs about two tons, and the shaft (which is as big as an ocean steamship's) about seventy-five tons, yet the water is to be introduced in such a way as to carry this load, aud leave to the various bearings merely the duty of holding the mechanism in position. Again, it is customary in the American dynamo to have the outer set of magnets, whether they be two or a hundred in number, and constituting what is called the "field," remain statiouary; and the armature with its coils, in which the current is excited, rotates inside of the cluster. But at Niagara the conditions are reversed. The central portiou will be fixed, and the outer part will whirl about it. The first desigus adopted by the company were prepared by Professor George Forbes; but the company, before taking the contract to build, proposed certain modifications.

The field magnets, twelve in number, are attached to the inner face of a wrought-steel ring. Their pole-pieces are also of steel. The riug, which is about twelve feet in outside diameter, is both supported and revolved by a plate which stretches completely across it, which is shaped like a flattish cone and which is secured to the upper end of the shaft. In this roof are several openings, covered with small rouuded hoods, to admit air. Every one familiar with the arrangement of a dynamo knows that field magnets are uot permanent magnets, but electromagnets; that is, the iron cores derive their magnetism from a current flowing through coils of copper wire around them. In a direct-cnrreut dynamo, after the machine is started and the armature coils begin to develop electricity by induetion, some or all of this current is lead off into the field coils; and from that time onward the operation is very simple. A small amount of "residual" magnetism remains in the cores after the machine stops, and this is the germ relied upon to start with next time. But in dynamos designed like those of the Niagara plant to develop au alternating current, it is customary to use a separate exciting current, derived from an outside sonree, usually a small direct-current dynamo. At Niagara the exciting curreut is brought to the field magnet coils through sliding contacts (brushes and collecting rings).

Before referring more particularly to the armatures adopted for these machines, a word or two might be said about the "disc" pattern of armature. Thereiu one does uot see a lot of spools of copper wire, each with a separate core. Instead, there is a thick dise, on whose periphery are a lot of transverse furrows or slots, giving it to the careless observer the appearance of a cogwheel. A eoil consisting of a few turns wound over a rectangular form is then applied to the disc in such a way that one side of the sqnare will fit down into one slot, the opposite side into another slot a short distance away, and the remaining sides lie flat on the lateral surfaces of the disc. Each coil overlaps several others, and conseqnently includes as its core part of the metal forming another coil's core. Right here it may be remarked that the word "core" is also used to designate the whole disc without its coils. It will be seen that, however this arraugement may differ from the older ones, the essential idea is retained: A piece of soft iron is encircled by copper wire, and the pole of the eleetro-magnet thus created points outward, radially toward the field magnet past which it is to be moved by rotation. Each groove in the periphery of the disc contains the first end of one coil aud the further end of another. Sometimes what is called here a "coil" consists merely of two solid bars of copper, each in a different slot, and having their ends properly connected. For reasons which need uot be given, it is desirable to make those bars of several strands, lightly insulated from each other. Of conrse each bar is also insulated carefully from the one with which it is required to lie in the same slot. In the Niagara generators the armature is a horizontal ring, composed of thin plates of oxidized iron, lying one above another, and bound together by eight vertical bolts of uickel steel. There are 187 holes or slots in its periphery, aud two rectangular copper bars, insulated with mica, are fitted into each. Two kinds of counections are theu provided, one making coils out of the bars and the other merging the various coils together, not, however, into one, but into two systems, for these are "two-phase" dynamos. That is, they develop two alternatiug currents, one having its changes come a quarter of a pulsation behind those of the other for convenience iu operatiug the "two-phase" motors, which some of the customers are expected to use.

From the framework that sustains the armature there extend inward four arms to provide bearings for the shaft. The bushings of the beariugs are provided with zigzag grooves for oil, while the outer surface of the bushings have other grooves through which water may be circulated to keep them cool.

Some of the local consumers at Niagara will want a continuous current instead of an alternating one. Several novel machines to effect this conversion, besides transformers to lower the voltage to the desired degree, will therefore coustitute part of the equipment of the power house. Again, while the dynamos will deliver their output at 2000 volts, there has been talk of raising this to 5000, 10,000 or even 20,000, for ease of transmission to distant points; and other transformers will also be required for this work. Some of the details of the mode of distribution, though, are not yet fully determined.

The field magnets are to be whirled about the armature 250 times a minute, or four and one-sixth times a second. As a separate impulse is excited in the armature by each field magnet, the frequency of the alterations will be fifty to the second, giving twenty-five complete waves in that period of time. No commutators or collectors will be required in order to lead these currents off, since the armature and its coils are stationary.

As soon as the plant is in operation the Pittsburg Reduction Company, which has established works at Niagara for obtaining aluminum electrolytically, will be furnished with all the electricity it wishes.

The Carborundum Company will be the next customer served. But it is hoped at an early day to deliver a good supply in Buffalo, which city is preparing to celebrate the event with much formality and display. It is designed to include Lockport, Rochester, Syracuse and other large and small centers of population within the field of these benefits, eventually, besides furnishing electric light and power to industries to be established at Niagara, and operatiug boats on the Erie canal with the same agency. As the capacity of the outflow tunnel from the wheelpit will accommodate water enough to generate over 100,000 horse-power, it will be necessary only to install more turbines and dynamos to meet any demand up to that limit. But the same corporation controls rights on the Canadian side of the Falls, and is already taking preliminary steps toward the development of an even greater amount of power there than the American plant is adapted to yield.

Compared with the enormous amount of water going over the Falls, which is equivalent to something between seven and twelve million horse power, the portion taken for this enterprise is so small that it will probably make no perceptible difference with the appearance of the mighty cataract. Even in winter, when the accumulations of ice up in the rapids sometimes interfere with the supply on the American side, it is believed that gravitation would make good any artificial deficit due to the power company's consumption.

Direct Current Dynamos.

There exists in England a general and deeply rooted idea that direct current dynamos of very high potential are not at all practical. This unfavorable opinion is particularly strong in regard to the use of such machines for the transmission of power for any considerable distance—in fact, such a system is considered to be almost out of the question. The actual historical and practical facts are that the high potential direct current machines were more exteusively and successfully operated when the dynamo first came into general use about 1880 than any other type, either direct or alternate. Furthermore, their number and size have largely increased, and the voltage at which they can be practically worked has been steadily raised, until the public now have sixty-light dynamos as the staudard size of large machines generating about 3,000 volts and ten amperes. Arc dynamos of ninety-light capacity are also regularly made by several manufacturers, and 120 or even 125-light machines are built and used.

An Eastern syndicate is prosecuting a survey in Kern canyon, and a party of twenty men is blasting out a trail, beginning about fifteen miles northeast of Bakersfield, the intention being to spend $8000 or $10,000 in a preliminary survey to determine the feasibility of developing electrical power there. It is expected that the survey will be completed by February 1st. C. N. Beal is in charge of the project. The California combination of dear fuel and unlimited water power makes an inviting field in the mining districts for the utilization of mountain streams in furnishing electric power.

The phenomenon known as "electric sunstroke" is attracting attention by reason of its frequency among workmen employed in melting metals by the electric process. The intense voltaic arc between the carbon and the metal to be melted emits rays, producing a sensation similar to that of a burn on uncovered portions of the body. There is frequently great pain, sleeplessuess, and in some cases fever. The skin becomes copper-colored or bronzed, the eyesight is sometimes temporarily lost and followed by what is known as "yellow vision," with a seusation as of sand under the eyelids.

The German military authorities are trying a new arrangement of the electric light. An electric arc lamp of 5,000 or more candle power is suspended in the air from a captive balloon. The current is led to the lamp by an insulated wire or cable, and the light is reflected downwards to the ground. A large open space is thus illuminated, without lamp-posts, and the evolutions of a body of troops can take place by night without impediment.

A paper read before an institution of standing, but inadequately discussed, may often do more harm than good.—London Electrician.

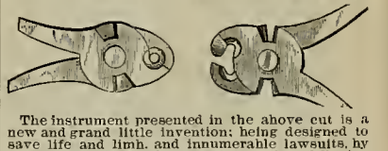
Tacoma, State of Washington, U. S. A.

GIANT POWDER FUSE CAP FASTENER.



The instrument presented in the above cut is a new and grand little invention; being designed to save life and limb, and innumerable lawsuits, by doing away with the dangerous operation of digging out wet and unexploded loads, where Giant Powder is used in mining. The instrument is made of the finest cast steel, and crimps the cap on the end of the fuse *firmly* and *absolutely water tight*. There is also a Fuse Cutter attached. Price 75c. each.

LIGHTNING / LARGEST WELL MACHINERY Works.
All kinds of tools. Fortune for the driller by using our Adamantine process; can take a core. Perfected Economical Artesian Pumping Rigs to work by Steam, Air, etc. Let us help you. THE AMERICAN WELL WORKS, Aurora, Ill.; Chicago, Ill.; Dallas, Tex.

A Titled Metallurgist.

The recent death of Lord Swansea ends the honorable career of a busy man who did much for mankind. He was on this coast last fall. The life and labors of this peer of the British realm contain an element of more than passing interest. He was what is sometimes in England termed a "laboring lord." For more than fifty years he worked with indomitable energy in the building up of one of the largest industrial enterprises on earth. The possessor of a title and vast wealth, there was little of the aristocrat about him. His friends were among the masses very largely; there were few among the thousands of men who labored on his great estates but admired and loved him. Lord Swansea was a man of genial nature and kindly heart. The poor in his borough were his especial eare. It is said that among the laboring classes he was the most popular peer in all the British realm.

Lord Swansea was born at Singleton, Wales, in 1821. He graduated at Eaton in 1842. The following year he took charge of the extensive business of Vivian & Sons, Liverpool. Three years later he assumed the management of his father's business at Swansea. The operations at that time were confined to copper smelting; but he developed the manufacture of spelter, or zinc, introducing an entirely new system and raising the production enormously. In 1846 Lord Swausea, theu plaiu Hussey Vivian, commenced the extraction of silver from copper by a process which he perfected. In 1850 he introdueed the Platner process of extracting gold. Five years later, under his direction, the great works at Swansea begau turning out nickel aud cobalt. In 1846 he undertook to deal with the extremely difficult problem of condensing copper smoke and produeing valuable products therefrom. His lahors in this respect were sueeessful in a marked degree. In order to utilize the sulphuric acid caused by the eondensation of copper smoke, Lord Swansea found it neeessary to erect alkali works, works for refining sulphuric acid, also superphosphate works. These were all novelties in their day.

The town of Swansea is the parent home of the smelting industries of the world. Lord Swansea was without doubt oue of the greatest metallurgists of the eentury; the study of metals and the methods of treating ore beeame a passion with him. There is not a mining eamp in America where his name is not familiarly associated with these subjects. He was a recognized authority upon the subjeets of mining; there was a time wheu most of the orc mined in any part of the world was sent to Swansea to be treated in the mammoth works which the ability and energy of this remarkable man praetically established.

Deep Snow.

The depth of snow on the high Sierras at this seasou of the year and after a heavy storm is almost incredible. Travellers through the mountains have observed with wonder shingles nailed upon the sides of trees from fifteen to twenty-five feet from the ground, and question whether the snow ever fell as deep as indicated by these shingles.

Mr. E. A. Halstead, who crossed the mountains many times for twelve successive years between Oroville and Quincy, says during the severe winter of four years ago snow fell to a depth of forty feet from Buekeye to the Toll Gate; that on one oeeasion the mail carrier, after a hard storm, crossed over the peak of the Buekeye House without seeing the building, although it reached a height of thirty-eight feet above the ground. The Letter Box hotel was so completely covered that it required thirty-two steps from the top of the snow down to the second-story window. For a distance of two or three miles in the vicinity of the Letter Box where the snow had drifted the banks were fully 100 feet deep. He notieed in one plaee where the wind had swept the snow from about the bole of a tree that it was fully ten feet down to one of the shingles to whieh we have alluded. He and others who were familiar with the snow that winter estimate that, had it beenmeasured as it fell, it would have reached a depth of at least 140 feet.—Oroville Register, Dec. 27th.

HORSE OWNERS should understand that their auimals are peeuliarly liable to iujury from contact with electrie currents. This is not due to the physical strueture of the horse, but to other causes, some of which are in a degree preveutable. The safety of a horse depends upon the skill of the blacksmith to some extent. The authority named points out that the shoes offer a large surface for contact and the nails eonduetors by which the current may enter the body, although the sole of the hoof itself is an insulator. The auimal's weight aids the contact, and a wet fetlock increases the danger. Blacksmiths, therefore, should not drive the nails to the "quiek" and the fetlocks should he trimmed.

20-Stamp Mill for Sale.

In Southern California, a 20-stamp Gold Quartz Mill, with engine, boiler, self-feeders, rock-breaker, etc.

As the premises are adjacent to Railroad, the Mill could he conveniently removed. Can be had at low price for cash. Address: "Quartz Mill," care MINING AND SCIENTIFIC PRESS, San Francisco.

Market Reports.

The Markets.

SAN FRANCISCO, Jan. 10, 1895.

The 60 mark has been reached during the week, in silver. Financiers in and out of Wall street are now giving serious consideration to the question of what would happen if Japan should lusist that China pay the war indemnity in gold or silver. As has already been announced, Japan proposes to make a demand upon China for an indemnity of something like 500,000,000 yen. The unit of account in Japan is the yen, of which there are three kinds—gold, silver and paper. The silver yen is about the size of the American standard dollar. It contains a trifle more silver, being composed of 416 grains, 900 fine, while the American dollar contains 412½ grains of like fineness. The gold yen is a very small fraction lighter than the American gold dollar. It contains 25½ grains of gold of 900 fine, while the American gold dollar is composed of 25.8 grains. The paper yen, which circulates only in Japan, occupies a place similar to our greenback and national bank currency. It is convertible into silver. But little is known outside of the empire in regard to the fiscal policy of that country. Prior to the present war with China the Empire of Japan had in circulation something like 24,000,000 paper yen, which were convertible into silver.

In addition to this the Bank of Japan had about 105,000,000 yens in paper in circulation, which was also convertible into silver. There was no uncovered paper in circulation in the Empire prior to 1893. Japan's system of coinage corresponds very closely to that of the United States, with the yen as the unit of account. The subsidiary coinage consists of the half yen, quarter yen, twentieth yen, with minor bronze coinage. The largest gold coinage is the five yen. Japan possesses gold and silver mines, which belong to the imperial house. They yield about $2,000,000 annually. It is now the belief of those who have been watching the struggle between the two nations—China and Japan—that the latter will exact the indemnity above alluded to in gold. In such an event it does not require a prophet to tell what will occur. To exact five or six hundred million yen in gold from China, a nation that is on a silver hasis, means rough sailing for nearly every nation in existence that is on a gold hasis. The nation that would first feel the effects of such a demand would he the United States.

New York Prices.

NEW YORK, Jan. 10.—Following are the closing prices for the week:

Mining Share Market.

SAN FRANCISCO, Jan. 10, 1895.

There was a strong market for Comstock shares during the week. The Con. Cal. & Va. declared a regular monthly dividend of 25 cents per share, payable next Tuesday. The annual election of officers of the San Francisco Stock Exchange takes place next Monday. The following nominations have been made: George I. Ives, president; A. B. Ruggles, vice-president; O. V. Walker, chairman; F. W. Hadley, secretary; George T. Marye Jr., treasurer; committee on membership, George C. Hickox, James Paterson, H. H. Shinn, Joseph B. Dyer, Charles H. Stoutenhorough, Charles D. Laing and J. B. Fitch.

The following shows the cash balances of some of the mining companies on the 7th inst.:

Alpha	$8,172	Julia	$96
Alta	3,118	Kentuck	2,843
Andes	9,254	Lady Wash'n	2,625
Belcher	2,816	Mono	3,690
Best & Belcher	20,722	Mexican	629
Bullion	5,436	Navajo	202
Bodie	17,066	Nevada Queen	495
Caledonia	3,875	Occidental	752

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING JANUARY 1, 1895.

531,990.—BICYCLE CANOPY—M. W. Armstrong, Los Angeles, Cal.

531,885.—BALING PRESS—H. Bailey, Willamina, Or.

531,779.—CARBURETOR—E. R. Cook, Sacramento, Cal.

531,780.—CARBURETOR—E. R. Cook, Sacramento, Cal.

531,791.—METALLIC BUNG—M. Fischer, S. F.

531,918.—BICYCLE—J. Forrest, Medical Lake, Or.

531,930.—CAR—C. S. Hardy, San Diego, Cal.

531,696.—ERASER—C. R. Pechin, S. F.

531,857.—FLOUR SCOOP—M. E. Peterson, Igo, Cal.

531,807.—GAS ENGINE STARTER—J. W. Raymond, S. F.

532,013.—FURNACE—A. Ropp, S. F.

531,650.—TELEPHONE INDICATOR—Sabin & Hampton, S. F.

531,812.—LABEL MANIPULATOR—J. Stites, Salem, Or.

531,815.—CLOTHES DRIER—Geo. Wade, San Diego.

531,818.—VOTING MACHINE—H. Weber, Temescal, Cal.

531,672.—VEHICLE BRAKE—G. W. Wise, Warner Lake, Or.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

METALLIC BUSHING.—Maximillian Fischer, San Francisco, Cal. No. 531,791. Dated Jan. 1, 1895. This device consists of a hung hushing, having on its inner edge lugs for engaging the jaws of an insertable wrench, whereby the bushing may be easily removed. The wrench has expansible and contractable jaws adapted to enter into and engage the lugs of the hushing, to unscrew it, and it has also a threaded stem for engaging and screwing the hushing into place. There is also a protecting plate to lie upon the bung stave about the bung hole. The disadvantage of the ordinary hung is that the hole in the stave being large, it weakens the stave in the absence of a protecting plate, and the bung hole is injured hy the rolling around of the keg, its pressure against its neighbor, and the rough handling it receives in general. Another disadvantage is the impossihility of removing the ordiuary bushing without breaking the stave. This invention remedies these objections and disadvantages by providing a bung hushing which can hoth be inserted and removed with facility, and by providing a protecting plate for the hung stave.

ROASTING FURNACE. — Alfred Ropp, San Francisco, Cal. No. 532,013. Dated Jan. 1, 1895. This invention relates to improvements in furnaces for roasting ores. It consists of a roasting chamher having an essentially horizontal hearth, a central longitudinal truck or car chamber exterior to the roasting chamber, and connected therewith by a narrow longitudinal slot, a car or truck, a means for impelling the same in the car chamber, a frame projecting through the slot into the roasting chamher, and a rake or rabble connected with said arm so that it will rake the material on the hearth at both sides of the slot. A cahle is connected with the car, and, passing around direction pulleys exterior to the furnace and the car chamher, acts to first move the car through the chamher with the rakes traveling through the roasting chamber, then carries it around exterior to the furnace, and again introduces it into the chamber at the opposite end. In conjunction with this apparatus are automatically operated doors which open to allow the passage of the car and rakes and close after such passage, and a mechanism by which the ore is fed into the furnace as fast as needed.

VOTING APPARATUS.— H. Weher, North Temescal. No. 531,818. Dated Jan. 1, 1895. This invention relates to an apparatus which is designed for the casting and recording of votes. It consists of a tahle having independent slots for the reception of disks, each of which represents a vote; independent receivers situated heneath each of the slots; chamhered guard hars adapted to receive the disks and direct them into their respective slots, and movable stops hy which the disks are supported and prevented from falling into the receivers, and a mechanism hy which the stops are removod after all the disks are deposited to allow the latter to fall simultaneously into the receivers. Guard covers are made to slide over the other slots for the same office, so that but one vote can he cast for each office, and suitable mechanism is employed for operating the stop plates to allow the disks to fall when all have been deposited. An indicating disk is connected with a mechanism to show how many votes have been deposited, and the disks are received into tuhular chamhered receivers having numhers to indicate the number of disks and votes in each of the receivers.

MINING

DIPLOMAS AWARDED. Courses in other trades, all including thorough instruction in Mathematics and Physics. Send for FREE Circular, stating subject you wish to study. to **The Correspondence School of Mines, Scranton, Pa.**

THE CALIFORNIA DEBRIS COMMISSION having received applications to mine by the hydraulic process from Mello & Costa, in the Spring Valley mine, near Cherokee, Butte Co., to deposit tailings on flat ground; from H. E. Picket, in the Kentucky Flat mine, near Georgetown, El Dorado Co., to deposit tailings behind a dam in North Otter creek; from Wm. Johnson, in his mine near Volcano, Amador Co., to deposit tailings behind a dam in Clapboard gulch; from El Dorado Water and Deep Gravel Mining Co., in the Henrietta mine, near Placerville, El Dorado Co., to deposit tailings behind a dam in a dry ravine; from Leroy Hedge, in his mine near Brownsville, Yuba Co., to deposit tailings behind a dam in a ravine; from Rolland & Vanderburg, in the Epley mine, near Placerville, El Dorado Co., to deposit tailings behind a dam in a ravine; from the York Mining Co., in its mine near Brownsville, Yuba Co., to deposit tailings behind a dam in a ravine; from Hancock & Daly, in the Last Chance mine, near Placerville, El Dorado Co., to deposit tailings behind a dam in a ravine; from Goodman Bros. and Goodman & Bund, in their mines near Volcano, Amador Co., to deposit tailings behind a dam in Ashland creek; from Hadley & Bolles, in the 49 Flat mine, near Volcano, Amador Co., to impound tailings behind a dam in 49 gulch; and from G. A. Melnecke et al., in the Fine Gold mine, near Vallicita, Calaveras Co., to impound tailings behind dams in a dry ravine, gives notice that a meeting will be held at Room No. 92, Flood Building, San Francisco, Cal., on Jan. 14, 1895, at 1:30 P. M.

Notice of Assessment.

REED MILL AND MINING COMPANY—Location of principal place of business, San Francisco, California. Location of works, Ferguson Mining District, Helene, Lincoln County, Nevada.

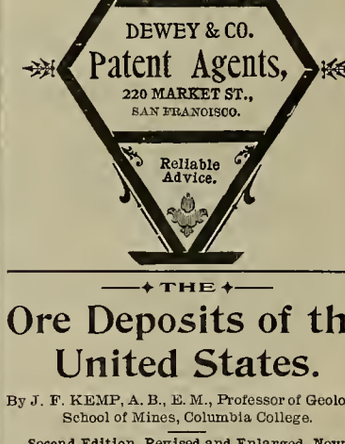
Notice is hereby given that at a meeting of the Board of Directors, held on the 31st day of December, 1894, an assessment (No. 1) of two (2) cents per share, was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, room 33, tenth floor, Mills Building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 28th day of February, 1895, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on WEDNESDAY, the 3d day of April, 1895, to pay the delinquent assessment, together with the cost of advertising and expenses of sale.

By order of the Board of Directors.

JOHN H. ISHAM, Secretary.

Office, Room 33, tenth floor, Mills Building, San Francisco, California.



THE

Ore Deposits of the United States.

By J. F. KEMP, A. B., E. M., Professor of Geology School of Mines, Columbia College.

Second Edition, Revised and Enlarged, New Illnstrations.

A practical review of tbe ore deposits of this country. A valuable addition to up-to-date mining literature, of value to the Pacific coast. Sent postpaid upon receipt of price, $4.00. Address

Mining and Scientific Press,
220 Market Street, San Francisco. Cal.

DIVIDEND NOTICE.

THE GERMAN SAVINGS AND LOAN SOCIETY

526 California Street.

For the half year ending December 31, 1894, a dividend has been declared at the rate of five (5) per cent per annum on Term Deposits, and four and one-sixth (4 1-6) per cent per annum on Ordinary Deposits, payable on and after WEDNESDAY, January 2, 1895.

GEO. TOURNY, Secretary.

AGENTS $75 A WEEK AT HOME, using or selling **PRACTICAL PLATING DYNAMO.** The modern method, used in all factories to plate new goods. Plates gold, silver, nickel, etc., on watches, jewelry, table-ware, bicycles and all metal goods; fine outfits for agents; different sizes; always ready; no battery; no toy; no experience; no limit to plating needed; a great money maker. **W. P. HARRISON & CO., Clerk No. 15, Columbus, O.**

An Unwise Law.

The county clerk has recorded nearly 700 lodes upon which annual work has not been done. This represents a loss to the laboring miners of nearly $70,000, as fully sixty per cent of those who took advantage of the law are non-residents and amply able to pay for the work, while a majority of the remaining forty per cent were also able to have the work done. The law is against every interest in mining so far as Clear Creek county is concerned. It prevents the employment of labor when the miner is in the most need of it, as well as the development of lodes and the finding of paying ore bodies.—Georgetown Courier.

THE Geographical Society of the Pacific will hold its annual election for directors and councillors January 15th. The paper promised by the Hon. Jeremiah Lynch, on the recent discoveries in Egypt, is not yet completed for the society. We learn that Professor Schaeberle, the well-known astronomer of the Lick Observatory, is also expected to address the members at an early date.

PRACTICAL ENGINEERING SCHOOL,
205 Goodnough Bld'g, Portland, Or.
Civil, Electrical, Steam, Mining, Assaying.
Full charge of plant taught. Circular.

RUPTURE!

IT has been considered by the medical profession that hernia—commonly called rupture—was incurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But DR. J. C. ANTHONY, of 86 and 87 CHRONICLE BUILDING, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patient no pain, and those living near enough do not lose any time only while in his office once or twice weekly. He guarantees every case he treats, and does not ask a man for a dollar unless he cures him, so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medical College, of New York City.

INVENTORS, Take Notice!

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S.F.

Mining Reports and Mine Salting.*

NUMBER II.

By WALTER McDERMOTT.

Mine Salting.—There are all degrees of "fixing a mine"—from the legitimate showing of its best features by not taking out all the rich ore before offering for sale, or by varying degrees of skulduggery up to the palpable salting of mines, dumps and expert's samples. In the less illegitimate stages much can be done, and very frequently is done, in the way of a judicious stoping of faces in good ore, and by the observing of a discreet silence as to past weaknesses and irregularities of the ore deposits. In such cases it is simply the ordinary commercial position of "let the buyer beware," and the expert has to show by his report if he has experience, observation and sense enough to form a sound judgment as to value.

In a mine which is thus carefully prepared for selling, it is not at all uncommon for the owner to go beyond the legitimate limit already indicated, and to misrepresent facts by filling up or concealing old workings which would, if examined, produce an unfavorable impression. The next step in the downward path which leads to a hotter place (but in the meantime also sometimes to affluence) is the scooping out of the inside of apparently solid blocks of good ground by openings afterward filled up or timbered over. Some of the most experienced mining men and engineers have fallen victims to this and the previously described course of conduct, while some have just escaped being caught by a mere accidental indication of the fraud, or by "peaching" of some miner who helped in the work and had not been squared. Naturally the danger from the sources mentioned is much less in new mines of limited extent than in old mines extensively developed. In a mine which has been worked for some time the visiting engineer is at a great disadvantage as compared with the men who have worked in it for years, and perhaps devoted their greatest skill to making not only a good record, but to concealing the exhaustion which is approaching. It happens occasionally, also, that the owners complete their work by "picking the eyes out of the mine" in the interval between the expert's report and the turning over of the property to the purchasers. The richer the nature of the pay ore in the mine the greater the danger from this piece of rascality, which needs specially providing against in the terms of purchase and by other precautions.

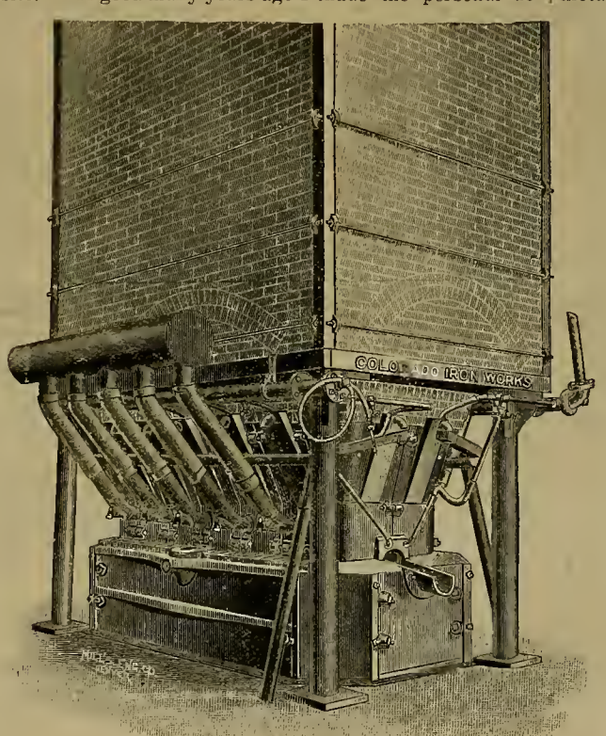
The above mentioned very real and not uncommon dangers, against which the engineer has to guard, are not, however, "salting" in its proper and technical sense, which is generally understood as covering any interference with the expert's chance of arriving at a true estimate of the value of ore. The salting may be done on the ore before the expert's arrival, or during his sampling, or on his samples when taken, or while panning or assaying.

Although cases are well known of faces in a mine being salted with such success as to catch the unwary, this form of salting is usually too difficult to carry out, and too superficial in character to offer much chance of catching an old bird. With ore dumps and alluvial deposits it can be done with better chances of success, but is naturally of an expensive nature if carried out on a really systematic plan. Cases are on record of successful salting of alluvial ground with precious stones as well as with gold, and the expert must clearly be on the watch against this, when circumstances allow of the possibility of its occurrence. With ore dumps it is often very easy to arrange a veneering of good ore over a very large pile of poor or barren rock, and then when the ingenious gentleman who takes samples "at random" comes along he will be sure to obtain a gratifying result.

A good many years ago I made the personal acquaintance of a prepared property on Lake Superior. It was a home-made tin mine. There had been rumors of valuable discoveries of tin ore on the north shore, where I was then living; and late one autumn an expedition from the United States went to report on it, taking an experienced Cornish mining captain for the necessary technical knowledge. A very glowing report was issued, and a company formed; rich samples were exhibited, and some tin run out of them and melted into spoons, which were presented to the fortunate shareholders. At that time the north shore was inaccessible for six months, except by a tramp of 200 miles on snow shoes to where I was, or 359 miles to the tin property, so the excitement grew during the winter, from the enchantment which distance lends. The report and the news of the excitement reached us in course of mail, and I was sent with an expedition and a land surveyor to report on the properties and take up land adjoining before navigation opened, and before any one else could reach the spot, which needed only 150 miles of snow shoeing for us. A good deal of ingenuity and work had been expended in making a tin vein, and a town

(Continued on page 38.)

* Paper read on Dec. 19, 1894, at the meeting of the Institute of Mining and Metallurgy.



SILVER-LEAD SMELTING FURNACE.

Silver-Lead Smelting Furnaces.

The accompanying cut was made from a photograph of one of the Omaha & Grant Smeltiug & Refining Company's latest furnaces in their Denver works, and is similar in important points to the silver-lead smelting furnace of to-day in the most successful equipments.

The furnace now in general use, as illustrated, bears little resemblance to that of sixteen years ago, when water-jacket furnace smelting was in its infancy in the silver mining regions of the Rocky Mountains, and is the outgrowth of the experience of practical metallurgists in charge of great smeltiug establishments built, owned and operated by practical business men.

The early furnaces were much smaller than now, and were usually circular in form, though not always so. They were confined pretty closely to the smelting of carbonate ores. Smelting grew quickly into a very profitable business, and the number of furnaces increased rapidily. Coincident with this increase of smelting capacity came a decrease in the output of strictly carbonate ores, and it became necessary to adapt the smelting furnaces to the treatment of other ores than the carbonates, which involved the use of roasting furnaces for sulphide ores, and may modifications in the detail of construction of the smelting furnaces, and a very great increase in size and consequence capacity, producing a corresponding economy in cost of ore reduction.

The Colorado Iron Works of Denver, Colorado, have made a specialty of the construction and erection of smelting works for the last fifteen years. They built the furnaces of the Omaha & Grant Smelting & Refining Co., of Denver and others.

A LARGE NUMBER of letters is daily received at this office makiug inquiry regarding mining sections, the purchase of machinery, the relative value of different processes, existing mining laws, assaying, etc., to which answers, so far as possible, are sent. Of late there are an unusual number of inquiries regarding aluminum. The matter is mentioned here to suggest that there is little use in sending samples of clay as illustrative of the presence and supposed value of the aluminum in it. Every clay bank is an aluminum deposit, hut not available or of practical value under existing conditions. There is a good deal of misinformation and some humbug about this matter. At preseut the bauxites and cryolites are the only paying sources of the light metal, and, despite the numerous "processes" announced, no one should build very high hopes on the possession of an ordinary clay bank regarding the aluminum it contains. Elsewhere is presented an article on the manufacture of aluminum by the Hall electric process.

RECENTLY it was stated in these columns that the best degree of puhlic policy required no more such "suspension of assessment" laws as those enacted in '93 and '94. This opinion is emphasized. Indeed, it would be better to so amend or interpret existing law as to put into practical effect what is manifestly true—that the working of a mine by its owners is a puhlic duty.

THERE is a noticeable preseut difference between the lethargy of the miuing stock market and the activity in actual mining operations.

REGARDING the disposition of stamps and cam shafts it may be said that if the stamps are allowed to rise and fall in regular succession from one end of the battery to the other, the material is apt to accumulate at one end, and the effective duty of the stamps thereby dimiuished. The order must, therefore, be varied. In a five-stamp battery a common arrangement is to let fall first the middle stamp, then the end stamp on the right, then the second stamp on the left, then the second stamp on the right, and, finally, the end stamp ou the left. The order in which the stamps are to fall being determined, it is carried into effect by fixing the cams ou the shaft iu such position that each cam, by the revolution of the shaft, will lift its respective stamp at the desired momeut. For this purpose the key seats cut in the hub of the cam must be determined with care: one common key seat beiug cut iu the cam shaft, when the desired position of any given cam has been determined, the key seat on the hub is cut to correspond with that of the shaft.

JIM WARDNER, who recently returned from South Africa, says that while there he spent a whole day examining the Crown Reef mine, and that superintendent Webber assured him that he had enough gold ore blocked out "to run that 240-stamp mill 150 years, and crush four tous per day to the stamp." Possibly. If so, that is cousiderable ore. Allowing that it runs $10 to the tou, that foots up 54,750,000 tous of ore, aggregating $547,500,000. Mr. Wardner, who, since the discovery of Mr. Webber and the Crown Reef and the tidy little block of ore referred to, has been visiting Colorado, says, writing from Leadville: "I saw more ore blocked out in the Little Johnny thau in the Crown Reef. The Little Johnny will go from $50 to $400." Possibly, also. Allowing $200 a tou for the alleged amount of ore Mr. W. says he saw in the Little Johnny, then that mine will turu out $10,950,000,000! It aud the Crown Reef will together produce about eleveu thousand million dollars. The eutire present total of gold on hand in the world is about four thousand millious. Sober consideration of the figures must lead to the couclusion that these two miues will occasion a readjustment of existiug financial couditions, or else Mr. Wardner or Mr. Webber or one or two other people must be mistaken. Probably the latter.

Not Proven.

The notice of this journal is weekly directed to novel theories and hypotheses in various fields, and while in many of them the ingenuity of the argumeut is alone deserving of commendation, in some the assertions challenge serious recognition and extended uotice.

Science, which is simply organized knowledge, has nothing fixed, traditionary or rigid about it. It is as elastic as the atmosphere, and as iconoclastic as the most zealous of image-breakers. Nothing is sanctified, nothiug definitely placed or displaced. It requires only proved results, the proof being of a uature satisfying intelligent minds.

Proof, absolute demonstration, accurate showing of fact, alone secures permaneuce or continued recognitiou. Where these are lacking the cleverest hypothesis, the most ingenious theory, falls, unsupported.

Mr. E. W. Keeler of this city at cousiderable length cites and paraphrases what is styled "a new system of philosophy," the result of much mental effort ou the part of Mr. S. J. Silverstein. The gentleman asserts that "there never was such a force as the force of attraction; that all the laws induced from this law of gravitation are utterly without foundation, and that Kepler's laws not only cannot be explained by Newton's law, but that those very Newton's laws serve as proof against it."

The hitherto general acceptance of Newton's deductions collides with Mr. S.'s argument, which is that there is what he terms a "centrality of motion;" that "motion is actually inherent in the planets themselves as in every substance or body existing in the universe; that motion was originally produced and is still being produced by a force outside of the planets; that a body has not a natural motion in it, aud when it moves, the motion must have been produced, and is beiug produced by a force outside of it."

If Newton's Principia be rejected, and his theory of centripetal force set aside, the true explanation of the phenomena Newton noticed will be looked for in a variety of speculations, among which that of Mr. Silverstein takes secondary place.

Mr. Stevenson recently brought out a new theory of centripetal force, or, rather, a theory of the persistence of energy, which substituted for the ordinarily accepted theory the hypothesis that a body moving in free space with independent motion has kinetic energy in the line of its motion and kinetic stability tending to prevent displacement transverse to its line of motion equal to its kinetic energy, and should a radical transverse force be applied equal to the kinetic stability, the body will then revolve in the orbit of a circle with a velocity equal to $\frac{v}{2}+v$, v being its original velocity, and according as the trausverse radical force is greater or less than the kinetic stability, so the curve will be one of less or greater stability, and the force of restitutiou will be less or greater.

As was once fiuely said by Prof. Tyudall, in an address before the British Association of Scientists, these questions will continue to be discussed by lofty minds "wheu you and I, like streaks of morning cloud, shall have melted into the infinite azure of eteruity."

Another philosopher, Mr. Julius Hensel, is to hand with a theme which he styles "bread from stones." He argues that a great and general mistake has beeu made in agricultural chemistry, and that since the first man uudertook to restore to worn-out soil the constituents that growiug crops extracted from it, the mistake has been perpetuated by applying the wrong kind of fertilizer. After an elaborate disquisition on the composition of animal and vegetable food, he argues that to make soil fertile it is only necessary to strew its surface with pulverized granite. He extols the beneficial results of the use of this "stone meal," and says: "It is now 400 years since the second half of the world was discovered, but the whole earth is only now discovered as far as the knowledge is concerned of how the inexhaustible treasures which are at our disposal in the nourishing forces of the rocks of the mountains may be utilized. Instead of workiug this colossal mine, men have bought the material of the fertility in the form of medicine; i. e., chemical fertilizers."

If Mr. Hensel's assertions are not antagouistic to the truth; if all that sterile soil needs is to have comminuted granite mixed with it to make it abundantly productive, he is a great human benefactor aud his discovery will revolutionize the world. The subject is of surpassing interest, for we must all eat, and when Mr. Heusel tells us that the use of 1200 pounds of "stouemeal" to each acre for each year for the space of five years will make sterile land fruitful, the possibilities are stupendous—that is, if Mr. H. is right. Trivial objections by those who make or sell fertilizers should not count. Where, as in this State, vast barren plains are bounded by equally vast mountains of granite, all so easily converted iuto food, the possibilities of increased food supply outrun ordinary imaginatiou, and the great problem of human sustenance is solved. It is a great point for the "Industrials" to kuow of such a possible combinatiou. Heretofore, azoic rocks have uot beeu looked upon as possessing any of the elements that enter into the composition of vegetable matter, aud it is probable that Mr. Hensel's theory may be combated by those who argue that the abseuce of carbon, nitrogen, lime, etc., in granite will seriously militate against its value as a fertilizer. Practical demonstration, successful experiment, will be necessary to convince the doubting that his theory is tenable. Like those who formulate systems of philosophy contradictory to the Newtonian theory of attraction, etc., the idea is more interesting than tangible, aud on each must, so far, be endorsed the verdict: "Not Proven."

THE mining returns for '94 show that the monometallists are having their way so far as silver production in the United States is coucerned—that the output of silver has been greatly reduced aud the output of gold very greatly augmeuted. Arizona produced three times as much gold as silver in '94. Colorado, looked upon since Nevada's decline as the silver State, has astonished the country with a gold output for the year of $11,000,000, aud in like manner with the other mining States and Territories. But the law of compensation runs through every line of life, aud though the total sales of silver certificates in New York in 1894 were only 95,000 ounces, against 2,626,000 ouuces iu '93, there not having been a single sale of silver in the board room from April 5, '94, to January 1, '95, yet the proper solutiou of this most important question cauuot much longer be delayed. Above and beyoud artificial restraints come public demands and requirements which are for the rightful recognition of silver, not as a matter of petty "protectiou" to the miner, but as one of necessary protection to the prosperity of the entire nation.

"DID the suspensiou assessment of '94 apply to incorporated compauies?" is asked by a Riverside subscriber. It certainly did. "Is machinery and plant on abandoned mine locatable?" asks an Arizonian. No. A failure to comply with Government requirements invalidates no ownership. Buildings, tools, machinery, etc., belong to the man who paid for them, and he can claim them auy time.

Personal.

COL. D. H. JACKSON is now superintendent of the Grand Victory mine, Placer Co.

ALFRED SWAIN has been elected secretary of the Union Con., vice C. C. Harvey, deceased.

W. D. CHAMBERS has been appointed superintendent of the Mitchell mine, Calaveras Co.

CARL KLEINSCHMIDT of Helena has received a diploma as professor from the Royal School of Mines at Freiburg, Saxony, the highest degree in mineralogy and metallurgy issued by that institution for the past fifteen years.

HON. JACOB H. NEFF, president of the State Miners' Association, is prominently mentioned among the candidates for the two years in the United States Senate to fill the vacancy occasioned by the death of Leland Stanford.

R. H. CAVILL left for Johannesburg, South Africa, last Sunday, where he will act as manager of the New Rand Mining Co. The careers of Hammond, Williams, Clarke, Clement and other California miners who went thither to superinteud important works illustrate the recognition by mine owners iu that far-off El Dorado of the value of practical men.

E. C. POTTER of Chicago, president of the Illinois Steel Co., left here last Wednesday on the China for Japan, at the request of the Japanese Government, to teach the Mikado's subjects how to utilize their mineral resources and to perfect plans for the construction of steel works, the cost of which has been estimated at from $2,500,000 to $10,000,000.

Concentrates.

THE 50-stamp mill on the Grand Victory mine, Placer Co., is about finished.

THE North Bloomfield Company is reported to have bought the Catskill mine, Bangor, Butte Co.

E. B. TRUE has purchased the Knott mine at Warreas, Idaho, from ex-Governor Willey for $12,000.

THE Mammoth mine, near the Mokelumne, Middle Bar, is reported sold to an English company for $30,000.

THE Englehardt Gold Extraction Company of Denver will build a twenty-ton plant near Prescott, Arizona.

IT is the reported intention of Alvinza Hayward to put a 100-stamp mill on the Oro Fino, near Shingle Springs.

THE miners of Montana are deemed to have won a victory in securing the selection last week of Leo Mantle as U. S. Senator.

THE Aspen, Col., big silver mine closes this week, and will wait for an advance in silver before resumption of work.

THE reduction works of the West End Gold Mining Company at Sherman, Colorado, will be completed and started up about February 1st.

W. S. STRATTON of Cripple Creek, Col., says he will give $2000 toward a miners' hospital at that place if Dave Moffat will give an equal amount.

THE Consolidated South Spring Hill Gold Mining Company has incorporated, John R. Tregloan superintendent, to work the Medinn mine at Amador City.

THE Gold Flat mine has closed down on account of the great amount of water. The pumps have been utterly unable to keep the water down, says the Nevada City *Herald*.

THE Baker City, Or., *Democrat* points to the $17,000 gold output of the Virtue mine for December as an indication of what the mines of that county can do when scientifically managed.

C. A. PLUMMER of Portland has bought the Jewett mine, five miles from Grant's Pass, Or. J. A. Gowan will be the superintendent, and will put in new machinery of modern pattern.

MESSRS. BROWN AND PEDRO NEGRO have sold their share in the Amarillas mine, Sonora, Mexico, to H. Hinds, one of the proprietors of the Colorado Co., for $50,000 and $30,000 gold, respectively.

THE State Mining Bureau has sent circulars to every miner and mine owner in the State asking for a complete report as to the total output of the mines for the twelve months ending Dec. 31st, '94.

THE recent offer of Captain Griggs to take sacked ores from Johnson creek to Everett at a cost of $8 per ton is another huge concession to ore shipping in upper Okanogan, says the Loomiston *Journal*.

THE McCauley Gold Mining and Milling Co. of Crevasse, Park Co., Montana, are about to put in a complete twenty-stamp mill. The Oro Fino Co. at De Borgia, Montana, are building a five-stamp mill.

MONTREAL MEN are reported to have made an offer of $200,000, half cash, for the Clinton mine, near Jackson, Amador Co. S. M. Shortridge, of this city, is the owner. There is a fine lot of machinery on the property.

DURING '94 it is estimated 30,579 flasks of quicksilver were produced in California. The '93 product was 30,551 flasks. The '94 shipments by land and sea for the first eleven months of the year aggregated 28,060 flasks.

AT Candelaria, Nevada, the tailings of the Holmes mine are being tested by Colonel Sutherland, with a view to working them by a leaching process. There are half a million tons of tailings at Caudelaria and Belleville.

THE Georgetown, Col., ore samplers paid out $513,159 for ore in 1894, which had a gross value of $764,058, showing that thirty-three per cent of the value of the ore produced in that district went to pay smelting and freight charges.

THE Florence, Col., Reduction Works made its first test last week, and the machinery proved all that was expected of it. The success of the plant is viewed with satisfaction at Cripple Creek. To that gold camp it means a greatly increased output.

FROM the Altar district, in Sonora, it is reported that the Mexican authorities last week confiscated $20,000 in gold which was being taken out of the country without paying the export duty of ten per cent. There are about 2000 men on the grounds, mostly Mexicans and Indians.

THE new leaching plant for the Bi-Metallic at Phillipsburg, Montana, handles 700 tons of roasted tailings or 300 tons of dried tailings every twenty-four hours. There are 160,000 tons of these tailings from which the Russell process extracts 75,000 ounces of silver and $3000 in gold per month.

THE Kennedy district, Humboldt county, from the mines of which so much was expected last fall, is reported dull at present. There appears to have been mismanagement or a "freeze-out" at the mill erected some time ago. Some say that all will be well again as soon as certain mines have been bought.

THE Coolgardie gold fields are booming. One hundred and twenty companies have been floated from London, England, in the last three months, and 2000 leases have been taken up in Australia. The suffering from want of water at the mines is said to be horrible, and a great many deaths from thirst are reported.

THE returns for the Harqua Hala, Arizona, mines for the month of November '94 are: Crushed during the month, 3235 tons; estimated gross value of gold produced, $27,200; miscellaneous revenue, $500; total revenue, $27,700. The estimated total expense was $12,600, leaving an estimated profit for the month of $15,100.

AT Telluride, Colorado, on the 12th, Judge Gabbert made a decision, the first of the kind in Colorado, that operators of stamp mills must use reasonable means to prevent the flow of tailings into streams where others would be materially injured thereby. Both plaintiff and defendant excepted to the decision and the case will be appealed.

THE weekly yield of the Con. Cal. & Va. mine is about 350 tons, averaging $50 a ton. A body of ore is in sight extending from the 1650 down to the 1750 level, there being a continuous opening through the deposit between these two points. In drifting north and south on the ore body and in sinking upon it below the 1750, it is expected an immense amount of ore will be obtained.

THE Ajax (Utah) Mining Co. have under advisement bids for the erection of a 100-ton concentrator. They have sold 100,000 shares of the capital stock to Samuel McIntyre at a figure which would make the valuation of the entire property in the neighborhood of $470,000. Mr. McIntyre has been elected vice-president and general manager of the company, vice Henry Shields, resigned.

THE gold nugget in the turkey's gizzard has been provokingly slow in coming to light this season. It was due in Josephine Co., Or., a week before Thanksgiving, and should also have been heard from in western Colorado Christmas eve. It is only last week the regular item turned up, and in Helena, Montana, which furnished in two turkeys, bought by M. E. Nichols, nearly an ounce of gold and thirteen sapphires.

THE currency question has been solved at De Lamar, Nevada. The De Lamar Company has issued coins. The denominations of the coins are 12½ cents, 25 cents, 50 cents and $1. On one side is printed "Good for (whatever denomination) in exchange," and on the reverse, "At the Office of De Lamar's Nevada Gold Mining Company." Silver being very scarce, these coins are very handy in making change. The De Lamar Company redeems all of these coins. They are made of aluminum.

THE report of the Transvaal Gold Exploration and Land Co. shows the return of bullion to have averaged over 2000 ozs. per month, or a total of 24,676 ozs. for the year, as against 11,315 ozs. for 1893. The cyanide process has dealt with 8491 tons, yielding 9282 ozs. of bullion. The new twenty-stamp mill and the electrical plant are completed, and the cyanide plant is being added to. The aerial rope and tramways connecting the Theta and Chi workings with the new mill are now nearly completed, and will greatly reduce the cost of transport.

AT the Broken Hill Proprietary, for the week ending Dec. 20th, 10,156 tons of ore were treated, yielding 860 tons of lead, containing 225,431 ozs. silver; also 1150 tons, treated by amalgamating and leaching plants, producing 12,113 ozs. silver. A dividend of 1s. per share is declared, payable Jan. 10th. For the week ending Dec. 27th 10,661 tons of ore were treated, yielding 900 tons of lead, containing 224,823 ozs. silver; also 712 tons treated by amalgamating and leaching plants, producing 12,109 ozs. silver.

THE *Keystone* says that the mining community of Idaho is eager for a proper legislation for the promotion of the chief industry of that State. The present mining laws allow prospectors to locate ground without compelling them to do any work upon it for a long period of time. As the laws stand now, a prospector can locate thousands of acres of mineral ground, have it recorded, and can hold this ground against all comers until the first day of January, 1897; and he can do this without any work on the ground.

ACCORDING to the Idaho *World* the Treadwell mine, in Alaska, will probably have to take second place when the Boulder, eight miles north of Idaho City, begins to produce to its full capacity. A crosscut has been run over 120 feet in solid ore, and is not yet across the ledge. The assayer for the company has been making assays all the way across, and finds that the ore runs from $8 to $10 per ton. The company (the Gund Gold Mining Co.) contemplates putting in seventy more stamps next summer. Their new thirty-stamp mill has begun crushing.

NEAR Kaslo, B. C., last Tuesday, three miners named Moore, McMillan and Mitchell, owners of the Eureka mine, were on their way to the mine and while climbing a mountain a mass of snow 20 feet deep and 200 yards in length became detached. The three men ran, but were all overtaken by the slide and carried along with trees and howlders to the canyon below, where the life was crushed out of them. Their bodies were recovered. Two miners who were working on the Silverton mine in the path of the slide are missing, and they were probably killed also.

THE Blue Lake Mining Company, that proposes to work 400 acres of placer ground twenty-five miles from Shoshone, Idaho, will use an entirely new milling process in the mine, known as the Bard amalgamating machine. It employs a riffled copper plate, and uses quicksilver. The company has five of the machines in use, and has been able with them to save 95 per cent of the gold, while handling from 700 to 1000 yards of dirt per day. The hydraulic equipment of the mine includes two miles of flume and ditch, with 1000 feet of eight-inch pipe line. The pressure is 100 feet. Water is drawn from springs which have a flow of 3000 inches.

AN explosion of giant powder appalling in its results took place at Butte, Montana, on the night of the 15th inst. A fire in the Butte Hardware Co.'s warehouse had gathered nearly the entire fire department of the city, and according to press dispatches several tons of giant powder in the Kenyon-Cornell Commercial Company's warehouse, illegally stored there, exploded, wreaking ruin and death. There were three several explosions. About 60 people were torn to pieces. Many more will die of the injuries received. The unfortunates were mostly so mangled that identification was impossible. A searching investigation is demanded and should be had.

THERE is a man in Salt Lake who claims that he has discovered a vegetable compound that "ripens" gold ore. According to his theory ore is ripened through the juices of the vegetation which grows above it. The rock may contain many thousands of dollars' worth of gold, but until it is ripened by coming in contact with these vegetable juices it is not discoverable by assays or otherwise. According to this genius, by treating gold rock with this solution the hearing capacity is increased at a ratio of about 18,000 to one. Ore that goes only a trace, after being subjected to this treatment will mill $17,000 or $18,000 per ton. If this theory prove tangible, gold will be demonetized, sure.

THE Gold and Silver Extraction Co. of America (Limited) have brought suit against the Mercur (Utah) Gold Milling and Mining Co., praying for an injunction to prevent defendants from using the MacArthur (cyanide) process of extracting gold and silver from ores and for damages. The plaintiffs allege that the defendant corporation induced them to enter into a parole agreement, whereby the plaintiffs instructed the defendants in the use of the process and assisted them in directing a plant for the operation of the same, and the latter agreed to pay a royalty of $1 for each ten tons of ore treated. From September 1, 1891, until August, 1893, the complaint goes on to state, the defendants acted under this agreement and paid more than $13,000 to plaintiffs as royalties, but after that period they ceased payment, and are now infringing on plaintiffs' letters of patent by using the same without payment therefor.

CLAUDE M. BENNETT tells the Idaho Springs *Gazette* that he went to the mint in the city of Mexico and asked to have a United States dollar weighed and compared with a Mexican standard dollar. The Mexican dollar went down in the balance, and the United States went up, showing the Mexican coin to contain more silver. A little later Bennett went into a restaurant. The dinner cost $1. He paid with a United States silver dollar. The restaurant cashier took his United States coin and handed him back a Mexican dollar, heavier than that from the United States; it was worth only half as much. In Texas, at the railway eating house, a meal costs fifty cents. Cross the border into Mexico and you are charged $1 for the same kind of meal, though if you tender a United States dollar in payment you will get back a Mexican dollar. The price is just the same practically. It does look, says the *Record*, as if the able financiers of the civilized nations had muddled things somehow when of two coins made of the same metal the heavier one is worth only half as much as the lighter one.

THE Australian *Mining Standard* always has a yarn about some alleged "American prospector." This time it is about one Adams who was "prospecting somewhere in the mountains in New Mexico." While wearily trudging along one hot day through the gulch, where the sun had a good chance at his back, he suddenly smelled smoke. The phenomenon struck him as odd, and he glanced quickly in every direction to ascertain the origin of the smoke; but, seeing nothing, he resumed his journey. A moment later the smell returned stronger than ever, and the breeze just then blowing in the direction in which he was walking, a light wreath of vapor curled about his ears, and gave him to understand that his haversack was on fire. Like all miners, he carried a large lens for the purpose of examining the specimens and the sand in his pan, and the truth flashed upon him. For want of room he had hung the glass on the outside, and the rays of the sun had been concentrated on his haversack, which was thus set on fire. As among its contents were twelve or fifteen pounds of powder, he lost no time in dropping the dangerous burden and getting away as far as possible before it exploded. The haversack fell between two huge stones and cuddled down out of sight. Adams soon reached a safe distance, and disconsolately watched the smoke arising from his sole worldly possessions. Suddenly there was a deafening report. The ground trembled, and Adams dodged behind a huge stone to escape the fragments of flying rock. Rising, he went to the spot to gather what he could find, when his eyes almost started out of his head at seeing the quartz that had been blown up fairly glittering with gold. His powder had done better on its own account than it had ever done on his, and had literally blown open a gold mine for his benefit. He was made a rich man in an instant, and named his mine the "Nick o' Time."

J. J. VALENTINE, of Wells, Fargo & Co., has issued his annual report of the precious metals produced in the States and Territories west of the Missouri river, including British Columbia, during the year 1894. His figures show the following aggregate: Gold, $45,892,668; silver, $28,721,014; copper, $22,270,294; lead, $8,223,513; total, $105,113,489. The value on which these totals were estimated was: Silver, 63 cents per ounce; copper, 10 cents per pound, and lead $3.11 per hundredweight. The production of the various States and Territories is tabulated and shows California, $14,188,582; Nevada, $3,100,560; Oregon, $1,711,662; Washington, $443,563; Alaska, $906,246; Idaho, $7,976,220; Montana, $30,250,000; Utah, $7,202,588; Colorado, $26,768,050; New Mexico, $1,871,359; Arizona, $6,995,831; Dakota, $3,045,909; Texas, $338,542; Wyoming, $45,000; British Columbia, $269,377. In addition to the foregoing there is also a tabulated statement of the annual products of lead, copper, silver and gold in the States and Territories named from 1870 to 1894 inclusive. There is also a statement of the product of gold and silver in the republic of Mexico from 1877 to 1894, values upon mintage basis, which shows the gold output of Mexico during those years to have been $17,939,000; silver, $600,145,000; total, $618,084,000. The exhibit of coinage of gold, silver and copper in the republic of Mexico from July 1, 1873, to June 30, 1894, was: Gold, dollars, $10,450,057; silver, dollars, $507,317,921; copper, dollars, $203,296; total, $517,971,274. The exhibit of the coinage of Mexico, from the establishment of the mint in 1537 to the end of the fiscal year 1894, shows the following totals: Colonial epoch, 1537 to 1821, $2,151,581,960; Independence, 1822 to 1873, $809,655,251; Republic, 1873 to 1894, $517,971,274; total, $3,479,208,485. The exports of silver during the past year to China, Japan and the Straits, etc., are shown as follows: From London, $47,502,180; from San Francisco, $12,520,678; total, $60,022,858, as against $67,715,485 of last year: pounds sterling estimated at $4.84. Mr. Valentine's figures give the gold output of California for 1894 at $12,540,646, as against $12,175,207 produced in Colorado. It is believed, however, that data now being collected will show that the gold output of this State for 1894 will more nearly approximate $15,000,000 in the aggregate.

Obituary.

C. C. HARVEY, for many years secretary of the Union Con. Mining Co., and connected with other mining companies, died suddenly on the 11th inst. at his residence in this city in the 69th year of his age.

ASSISTANT NAVAL CONSTRUCTOR GEORGE W. STREET, United States Navy, died in this city on the 12th, of pneumonia. He had arrived from the East but a few days before, for duty at the Union Iron Works. He was appointed from Wisconsin on July 1, 1889, and had until recently been attached to the navy yard at New York.

Live Oak Mine, Nevada County.

TO THE EDITOR:—A. McMahon, Jr., superintendent of the Live Oak mine, which is situated on the San Juan ridge, sixteen miles from this city, recently paid a visit to Nevada City. In a conversation with the writer he stated that the future of the quartz mining in that section of our county is very promising indeed. Most of the mines operating there have shown marked improvements in the past few weeks. Regarding the Live Oak mine he produced some very valuable and important data. From present indications it is one of the most promising and important of our new mines. When properly developed it will become a large and valuable bullion producer. The facilities for operating the mine cheaply are many and will undoubtedly cut a prominent figure in its future development. The mine is owned by a company of San Jose capitalists. Wm. McMahon of that city, father of the present superintendent, is the largest stockholder of the company and has given proof of his confidence in the property by investing a large sum of money therein.

The Live Oak is located on the same side of the river and in close proximity to the famous Delhi mine, from which such fabulous sums of gold have been extracted. The the locality is a favorable one no one acquainted with our county will deny. In fact, as I remarked last week in these columns, we anticipate great progress in this particular section of our county during the year upon which we have just entered, relative to quartz mining.

The mine is worked by tunnels, which make the mode of operating much less expensive. There are three tunnels penetrating the hill which can be used for practical purposes. The lower tunnel, through which operations are now being conducted, has been driven a distance of 600 feet into the hill. From the end of this tunnel to the apex of the ledge there is a vertical distance of 700 feet. This implies that they already have 700 feet of backs, or stopes, opened and ready for working. From the apex of the vein to the base of the hill there is a vertical distance of 1200 feet; and the fact that this immense body of ore can be extracted by tunnels would indicate a permanent and valuable property. The vein in places is fourteen feet wide, but the average width is about three feet. Some of the ore from this ledge has assayed as high as $400. Ninety tons of ore were crushed at the Delhi mill with a result of $7.20 a ton, not including sulphurets. The sulphurets are worth $102 a ton. The average mill test places the value of the ore at $7.50 a ton. The claim is 3000 feet long by 600 feet wide.

The owners of this mine have reason to feel proud of their possession. The facilities for operating it cheaply, as already stated, are many, and with the erection of a fine modern quartz mill, which can be constructed without heavy expense, the mine can be made very remunerative in a short time. Much credit is due to Mr. McMahon for the great interest he has taken in quartz mining in this district, and for the miner-like manner in which he has developed this mine. He has shown exceptional skill and mining ability in operating this property, and we believe that with the above mentioned improvements he will eventually have a great mine. SAMUEL BUTLER.

Mining Items from Shasta County.

REDDING, CAL., Jan. 10, 1895.

TO THE EDITOR:—The heavy rain in this section has furnished an abundance of water for gulch mining, and many a hungry miner is now a monometallist. The Niagara, now worked on the tribute system, has been making a fine record the past two months. The Myers property, under Prof. Morton's management, is working twenty men at present. The sale of the Iron Mountain property to an English syndicate has lapsed, the date for payment being January 1st. Some large commissions were connected with it that will not materialize. The Uncle Sam, on Squaw creek, drops thirty stamps steadily, and also runs a Huntington mill on soft ore. The Old Diggings keeps up a steady grind. The rich ore chute that yielded so handsomely a few weeks ago is commencing to get a little lean. Ore running $500 per ton was too good to last. The Quartz Hill is running ten stamps and also shipping ore to Selby's. The quartz milled is low grade but yields a profit.

The Sacramento river dredge, operated this summer by Destlehorst Bros., has proved the best paying investment in the county this season. On some days as high as $1500 was made at an expense of $12. The river bed is fabulously rich. The dredge does not save ten per cent of the gold.

A new era in drift mining for this end of the State has been inaugurated by the Parsons Company, operating in Oregon gulch. A year ago old man Parsons commenced sinking on the contact between sandstone and slate. He soon died, but his heirs kept on working, with the result that the gravel and gold in the seam got larger and richer. An incline 300 feet has been run, representing a vertical depth of 200 feet. They now have four feet of gravel that averages 70 cents per pan, and the bedrock still dipping.

Hydraulic work is about to be resumed on the claims about Horsetown, on Clear creek, which have laid idle for fifteen years. F.

Photographing Frost Flowers.

Written for the MINING AND SCIENTIFIC PRESS.

At this time of the year when Jack Frost draws his beautiful ferns and flowers on the window pane, who has not often wished that this beautiful work could be made permanent?

It will be interesting to the professional as well as the amateur photographer to know that it can be made permanent, and far more distinct than Jack Frost ever painted them, yet with all the beauty of every line and curve that is found in the original. But one must enter into copartnership with the frost king himself to attain the desired end. It is accomplished by the old wet-plate process. Here is the secret:

The glass plate is flowed with collodion and immersed in the sensitizing nitrate of silver bath in the usual manner. When removed from the bath it is put in the light-tight plate holder and placed where it will freeze. While frozen it is placed in the camera, focused on a white screen, and developed in the usual wet-plate way. The plate should be kept frozen till the developer is poured on. Beautiful border negatives can be made in this manner, and no two pictures quite alike. To produce different effects, the holder, when laid out to freeze, should be placed sometimes on end, sometimes on the side, and at other times on the face, flat down. The plate does not require very thorough draining when removed from the bath. Time of exposure in the camera will be governed to suit the artist's taste. Of course, a long exposure gives flat pictures. We have made negatives in one or two seconds that gave prints as distinct as a pen-and-ink sketch on white paper. We tried it without the use of the camera, by a slot admitting a streak of white light into the dark-room. The frozen sensitized plate was passed across the beam of light and developed as usual, but the result was not so good as in the camera.

HENRY W. BROWN.

Custer, Wash., Jan. 10, 1895.

The Crooke Process.

One of the processes recently brought to the attention of the public that promises to revolutionize the treatment of ore in mountain towns is the one called after its inventor, Prof. John J. Crooke. It is a modification and improvement on the old Augusta process, which was introduced in Germany half a century ago. It has been in use in Prof. Crooke's mill at Silverton, Col., for the past two years.

The ore is broken in a rock crusher and from there is fed to ten rapid drop, dry crushing stamps, where it is pulverized. The pulp is then mixed with a certain percentage of salt and roasted in an old-fashioned reverberatory furnace, thus converting the silver into a chloride. After lying on the cooling floor for twenty-four hours it is charged while still very hot into large leaching vats fitted with proper filters in the bottom. A very hot saturated solution of salt brine which has been strongly acidulated with sulphuric or hydrochloric acid, to which has been added a certain amount of a solution Prof. Crooke has not yet patented and the nature of which he keeps secret, is run upon the pulp and allowed to stand for about an hour, when it is drawn off on precipitating filters of peculiar construction. These filters consist of a series of square wooden frames about seven in number and each four or five feet square, arranged one above the other. To each of these frames a coarse burlap is tacked and in this is placed cement copper.

The brine solution, after passing through the ore, is conducted to the uppermost of these burlap filters, from which it percolates through the series and drops into the tank below. Immediately the brine solution containing the silver touches the cement copper the silver is precipitated, forming magnificent crystals that are often as much as two inches in length. An amount of copper goes into the solution in place of the silver and this is precipitated on scrap iron in the tank below the filters and thus recovered.

When the precipitation of the silver from the brine is completed it is carefully scraped off the remaining cement copper and melted into bricks, ready for the refinery or for shipment as the case may be. The cement copper, still containing a little silver, is used on other filters. The solutions are purified by crystallizing out the sulphate of soda and by precipitating the salts of the baser metals. This Prof. Crooke does but once in each season, treating from 1000 to 2000 tons of ore in the meantime.

Prof. Crooke claims that ores carrying even a considerable percentage of the baser metals can be treated by this process without difficulty. A mill is now being erected by Prof. Crooke at Pueblo.

African Diamond Mines.

Alfred Hale says the entire diamond-bearing district of South Africa has been walled in by a high stone wall, and nobody is allowed to pass in or out unless he is subjected to the closest scrutiny. Inside the walls are 10,000 negroes, who are secured for periods of six months at a time to work in the mines. The negros are fed corn meal, and are paid fifty or sixty cents a day. They come from the interior of the country, 500 or perhaps 1000 miles away, and are ordered to the mines by the chief of the tribes on the pain of instant death if they refuse. The agent of the diamond syndicate pays the chief a liberal amount for his aid in sending workers to the mines, and the poor, ignorant negroes have no alternative but obey. Once inside the gloomy walls the black man has no possible chance of escape, and he delves like a galley slave until his six months have expired. Then he is paid off, and the entire delegation from one tribe marches home across the desert in a body. It is seldom that a black is seen a second time in the mines.

There is a very satisfactory reason, so far as the individual is concerned, why he never returns. The diamond miner carries home with him money enough to buy several wives. If he is careful of his earnings he has enough hard cash to buy four wives, and that is the summit of his ambition. Any negro owning four wives is exempt from labor for the remainder of his days. He is known as a "gentleman," his wives do all the work for him, and he poses as one of the big men of the tribe.

This is, of course, a strong inducement for a black man to go to the mines, but the chances are that he will die from exposure or fall into bad company and lose his money, so the nabobs are not as numerous as one might suppose. Very little is known of what is going on in the interior of the diamond region. Every avenue is guarded by detectives, and a stranger caught loitering about in the neighborhood is liable to be sent to Cape Town for five to fifteen years, on the charge of buying stolen diamonds.

Mr. Hale said that the trade in stolen diamonds became so heavy a few years ago that the owners of the mines organized to drive the traders out of the country. The devices for concealing and carrying the diamonds out of the mines were remarkable for their ingenuity and their success. The law of the Dutch Republic required that any man charged with diamond theft, or purchasing stolen gems, should have the privilege of a trial by jury. As the majority of the jurors were generally engaged in the same shady transactions the convictions were very few and far between, and the country swarmed with country buyers. Fortunes made on the outside were larger than those on the inside. The mine owners bought up the legislators, and a law was passed requiring all diamond cases to be heard before three judges, who were given the power to send the guilty man to the breakwater at Cape Town for a long period of years.

The law has worked like a charm. The judges are said to be absolutely unapproachable from the standpoint of the diamond buyer, and a long procession of disappointed speculators has been marched off to the south, so that there are now not less than 1000 convicts from the diamond region piling up stones to keep back the ocean at Cape Town. Mr. Hale says it is the most disheartened body of men he ever saw, many of them being possessors of large fortunes. The edict has gone out against the diamond buyer, and he was practically not in the field this year at South Africa.

Of course, the European syndicate is correspondingly happy, but the Diamond Trust regulates the output at its will. Merchants and dealers at Kimberly are on the verge of bankruptcy, as they are under the eyes of paid detectives every hour, and their books are regularly inspected by officials of the Government, who are working in the interest of the European mine owners. The glory of Kimberly has departed, and the money which once went into the capacious pockets of the merchants now goes to enrich the gilded palaces of the European capitalists.

Aerolites.

These strange objects, which penetrate the earth's atmosphere from outer space, are stones containing a small percentage of iron alloyed with nickel. Twenty-six of the elements known to exist in the earth have been found in meteorites. In size they range from a grain of sand upward, but are seldom seen weighing over a few pounds. It is believed that millions of these small bodies, occasionally in swarms but often widely separated from each other, are flying through inter-stellar space. There are several resemblances, in their orbits and other respects, between the meteors and comets, and it is possible that a still closer relationship may yet be discovered. Proctor and others were inclined to think that the meteors had been ejected from once active volcanoes on the moon, and some astronomers have suggested that they were thrown off explosively by the planet Jupiter, our sun or other suns (the fixed stars). Such ideas, however, must be regarded as more or less plausible conjectures, and not as accepted facts.

A Thermostat Alarm System.

The object of the system illustrated herewith is for use on lines of shafting to detect the heating of the bearings, and thus call attention to it before it becomes hot enough to do any damage.

The apparatus consists of small instruments which are spaced on the ceiling of a room or any other place it is desired to guard against fire or excessive heat. These instruments are then connected by a system of wires to some central point, as the office, where an alarm bell and indicator are located. The bell instantly gives an alarm whenever the temperature in the vicinity of one of the instruments rises abnormally, while the indicator, which is, in principle, like the well-known annunciator, shows at a glance the exact location of the instrument which is overheated.

In an isolated factory it is customary to place extra alarm bells in one or two houses for night alarms, as, for instance, the house of the superintendent, then when an alarm is given they have only to go where the indicator, generally located on the outside wall, will show the exact location of the trouble. In cities it is customary to connect the

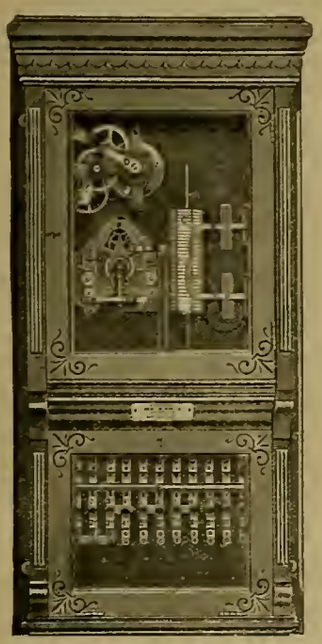

Fig. 1.

alarm with the nearest fire department house, and often with two separate houses. A circuit breaker *D* is then added, which causes the instrument in any building to strike a certain number on the alarm bell in the engine house; this shows the firemen exactly which building the fire is in. Such a device is, of course, necessary where there are a number of buildings wired to the same engine house. The exact location of the fire is then, as in the isolated plant, shown to the firemen on reaching the building by the indicator.

It is necessary in any such system to be absolutely sure that the batteries and the circuits are always in perfect order, and to accomplish this a very thorough system of testing has been devised.

Fig. 1 shows the testing case which is generally located in the office, and which is kept locked so that it cannot be tampered with. The clockwork *C* moves, at a uniform rate, the cylinder *C'*, which carries a roll of paper. The magnet *B* is connected with the outside lines, that is, any lines running outside of the building, as to the superintendent's house and the fire department house. The maguet *A* is attached to the inside wiring of the building. Now, by turning the lever *E* shown in bottom of case, all the circuits are tested. Those inside of building are put in series causing the current to flow through magnet *A*, pulling the armature and punching the paper in *C'*.

The outside circuits being in series, the current is diverted through magnet *B*, causing the armature to punch hole in roll, *C'*. The paper on *C'* is so ruled that the exact time in the week of the year, the day of the week and the hour of the day that the test was made can be seen by examining it.

The object of this mechanism is to give an accurate record of these tests, thus making it possible to see that the man having charge of the apparatus tests it as frequently as is required. It also serves as a record for the insurance companies, similar to the ordinary watch-clock record. The whole apparatus is so arranged that it is very difficult for an unscrupulous attendant to tamper with it and make up a back record if he forgets to make it at the proper time.

If in any case, on throwing the lever *E*, it is found that no record is made on the cylinder *C'*, it shows that there is a fault somewhere in the lines; then, by removing the top of the case, access can be had to the various circuits, so that the fault can be very quickly run down.

The system of wiring used in the buildings is a double system, the wires starting from the office where the testing apparatus, etc., is located, run through the complete circuit and return to the office again. With this arrangement, the cutting of a wire at any point does not disable the instruments which give the alarm, as there is always a connection back the other way. Fig. 2 shows the instrument which is placed wherever it is desirable to have an alarm given when the temperature gets above the proper point.

It is customary to set the thermostats so they will operate at about 140° (the usual fusing point of an automatic sprinkler is 160°), but this can be made much higher if it is desired to place them in hot places, such as dry rooms or on ceilings over boilers. Again, if it is desired to have them very sensitive, it is perfectly possible to lower their point of operation to 100° or even less.

The cut shown in Fig. 2 is enclosed, as shown in Fig. 3. For dry places this case is ordinarily made of wood, while for damp localities it is made of porcelain, having a porcelain cap which screws on to the base and entirely covers up all the connections, leaving only the bottom of the mercury cup projecting in a position where it is readily subject to heat.

Fig. 3.

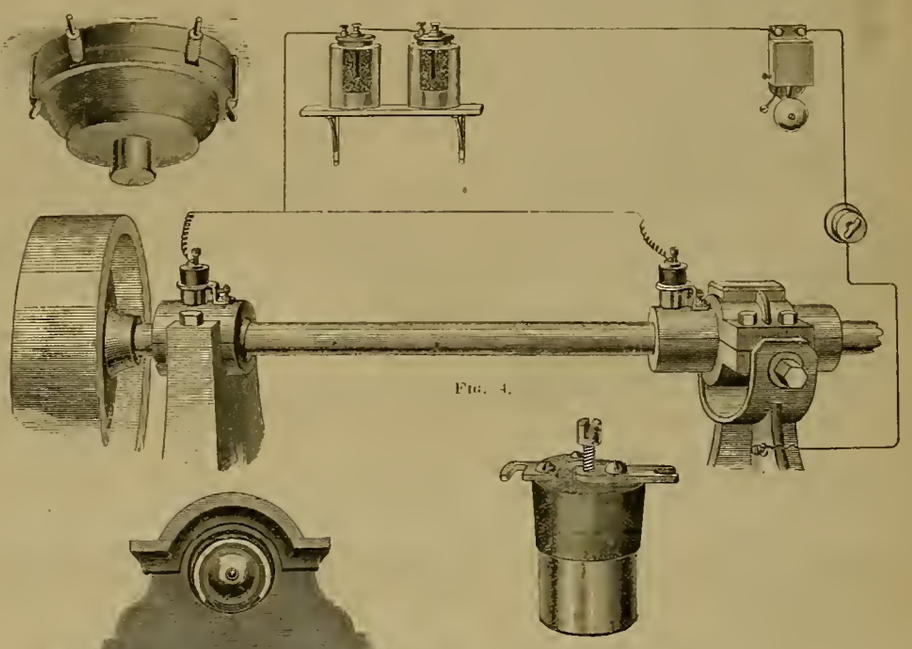

Fig. 4.

Fig. 2.

Fig. 5.

Another use to which this thermostat has been put is shown by Fig. 4. Here the little mercury cups are fastened directly to the top of the bearings of a line of shafting, the circuit being completed through an electric battery and an alarm bell, and whenever a bearing heats beyond a safe point, which point can be exactly determined by proper adjustment of the movable screw of the thermostat, an alarm is at once given by the bell.

Fig. 5 shows the indicator which is used with the journal bearing system, so that it may be ascertained at once from what bearing the alarm comes. This is accomplished by first numbering all shafts, or, perhaps, groups of shafts, and then wiring each one or each group back to the indicator board. Then the springs on the board from which these wires start are numbered to correspond, as shown in Fig. 5. When an alarm is given the lever handle is turned through the circle. The bell will stop ringing the instant the handle is moved from its normal position, but will ring again the instant the lever passes under the spring contact to which the circuit containing the thermostat giving the alarm is attached, thus indicating at once the point of trouble.

A Soft Thing.

The spies of the Anti-Debris Association are in this section. They ride out a few miles every day to exercise their horses, and to make a pretense of doing something for their employers. When they return to Yuba City they will probably take along two or three bottles of muddy water, as evidence that hydraulicking is being carried on in this vicinity.

There has been considerable hydraulicking done the past few days, and an immense quantity of debris has been washed into the creeks and rivers that are tributary to the navigable streams. This has been done in the face of the rule of the courts that no more debris shall be washed into these streams, but it has been done by a power that is higher than the courts, and which heeds not the edicts of man.

It is one of the immutable laws of nature that the water will run down hill, and people who live at the bottom of the hill are apt at times to get more water than they want, and with it a lot of extraneous matter that is carried along by the water. Hydraulic mining is not the sole cause of the trouble of the valleys, but nothing can make some of the people in that section believe but what it is responsible for it all.—Nevada City Transcript.

The Chicago *Tribune* says that in India the price of all commodities has advanced as silver has depreciated, and that the advance in wheat has been fifty per cent. The average price of what in the United States in 1873 was $1.20 per bushel, and as England imported during that year from India nearly 1,000,000 and from the United States about 6,000,000 bushels, we may reasonably assume that the price in India was about the same as in the United States, or say $1.20. If wheat has advanced fifty per cent in India since 1873, it must be worth $1.80 to-day. Last year England imported from India about 60,000,000 bushels. The average price of wheat with us was sixty-three cents, and according to the *Tribune* the average price in India was $1.80. Now, will our contemporary explain how it chanced that English merchants purchased so largely in India at $1.80 per bushel when they could get as good an article nearer home for sixty-three cents?

Dr. Heine Marks, a St. Louis hospital physician, claims to have discovered a cure for diphtheria which is superior to antitoxin. It is composed of two chemicals. One is applied by swabbing the throat and the other by a hypodermic injection. He asserts that this system is free from certain objections inhering in Professor Behring's plan; it never promotes abscess or decomposition by reason of a diseased condition of the horse's blood from which the serum is obtained, nor does it breed other microbes, as the antitoxin will if not properly or carefully handled.

Mining Reports and Mine Salting.

(*Continued from page 33.*)

ship had been surveyed in anticipation of the future rush for land. Some natural cracks in the country rock true fissure veins which Nature had overlooked when the mineral solutions were ladled out, had been filled up with a mixture of broken tin ore from Cornwall, copper tailings from Lake Superior, and soluble silicates for cemeuting material. Iu the camp of the promoters we found a barrel of the soluble silicates used.

In the meautime, the idea of the value of the discovery had grown so much that it seemed necessary to sell the property in London. The Uuited States could not hold it, and a financier—who was really a believer, was seut across the water. Curiously enough, he applied to people for whom I had previously made reports; aud on my return to headquarters, with the principal vein in my possession, I found a cahle askiug me to report how many millions it was worth, which I was able quickly and accurately to determine. Some years later in Colorado I was introduced to the gentlemau who planted the deposit with the explanation that I was the individual who had taken away his best lode in a small boat. The circumstantial report by the Cornish mining captain I have since heard explained by the fact that he was not accustomed to the particular braud of champagne used on the expedition.

My first report on a silver property in the same country was not calculated to breed confidence in min..g methods. I had left England with a full report by a government surveyor of the mine and its riches, but the claim was covered by the virgin forest—not a sign of outcrop or working—nothing to sample. There was nothing to report on but a magnificent crop of black flies and mosquitoes. The sanguine government surveyor had evolved his description out of his inner cousciousness, and aided by a ten-foot shaft on a small vein on an adjoining property. Since that time I have never felt a blind confidence in government surveyors as mining experts.

The salting of samples is, however, much more common than any other form of getting ahead of the expert. It is less expensive than salting iu advance, more deadly, and cau be nicely adjusted to circumstances and to the iudividual weakness of the victim. Wheu the owner of the mine, or any one connected with him, is allowed to assist in the sampling itself, there is no lack of opportunity with some ores for the artistic salting while in the mine; but, as a rule, engineers do not have the requisite faith in human nature to accept such assistance unless the character of the ore and kind of samples required make salting impossible at the time. In a strange district where assistance of some sort has to be obtained in breaking and transporting large samples, and the character of such assistance is not absolutely certain, the engineer must guard himself by duplieating entirely alone certain test samples. Assuming that samples have been secured without any chance of outside interference, the business is by no means ended, for the enterprising salter will follow those samples until actually pauned or assayed or taken out of his reach. I propose to illustrate some of these special dangers by the aid of a few personal experiences which will show that neither keeping samples locked up or sealed, or delivered to post-office or express company, will insure absolute protection iu all circumstances. In fact, to paraphrase a patriotic maxim, it may be said that "eternal vigilance is the price of freedom from salting."

To the successful cultivation of the art of salting, no great knowledge or experience of mining is necessary, any more than a study of architecture is essential to the practice of burglary. Trne ability will assert itself in this as in other employments by the inveution of new means to meet special cases, and by a proper discretion in regulating the dose of salt administered to the temperament of the patient. Sometimes the honest miner will freely relate stories of methods by which experts had been salted, implying delicately that no such schemes would be successful with his hearer, but reserving one, undescribed, for purposes of personal illustration later. As an example of the unexpected, which may oceur after samples have been safely removed from the mine, I may refer to a case in the Rocky mountains, where I had taken some samples to the nearest town and made arrangements with the loeal assayer for the use of his office. I preferred to make my owu assays, not from any chance of his kuowing where the samples were from, but rather from a distrust of his somewhat rule-of-thumb methods. I allowed his brother professional to continue his work while I did mine; aud, although apparently quite satisfied that I should pay him for the assays and do the work myself, his feelings must have been injured, for he doctored my samples without any other possible motive.

This inhospitable action caused me some annoyance and extra travel, but otherwise fortunately had no serious results beyoud somewhat lessening in me the proper Christian belief in one's fellows.

It is remarkable how generally the elementary knowledge of salting is distributed over the earth. Wherever mining is, there the salter is likely to be developed, regardless of differences in climate, language or religion. The art is not unknown in England. Not long ago I was asked to look at a gold placer in Wales, and though I should not have picked the country myself for exploring purposes, the terms offered left all the risk on the other side—so I went. The owner took me over the ground, aud I industriously panned in all the likely spots pointed out with never a color to eheer my heart. The owuer delicately intimated that perhaps I was not much of a hand at panning, and, further, that my gold pan was a poor contrivance. He thereupon sent up into the mountains for a certain Welsh mining captain, who duly came down with a Mexican wooden batea, and promptly produced good prospects from various places. He was so very skillful that when I gave him a sample of my own tailings from tests before he arrived, without mentiouing their source, he got a fine healthy show of gold even from them. When I mentioned that he had been working on wbat I washed out without getting a color, the Welshman was so confident of the fault being on my side, that I took half of the next sample he was about to wash and showed in my pan a better prospect thau he did with his half.

(*To be Continued.*)

No Occasion for Spies.

The second annual report of the United States Debris Commission, which has recently been submitted to Congress, contains many items of interest to the people of this part of the State, comments the Marysville *Democrat*. The Commission require each mining company that operates a hydraulic mine to report to them monthly, iu whieh tbe amount of earth washed and inches of water used is stated in in detail. W. B. Storey, a competent and trustworthy assistant, has visited and inspeeted the mines of tbe district during the entire season, watching not only the mines operated under permit but those that have not yet constructed restraining dams or settling reservoirs.

The Commissiouers have visited the miues in person where applications have been made for permits, and they have used due diligence to enforce the provisious of the law. The inspections and reports, say the Commissioners, relate to the effectiveness of restraint of detritus, and include observations of the quantities of materials escaping to the water cources. A system of observation has also been developed by the use of the hydrometer, which gives in a ready manner that proportion of escapiug material that can, for the purposes concerned, be regarded as soluble. This refers to the clays or to sand iu exceedingly minute grains. This character of material can be stored only in cases where a period of rest can be secured behind barriers. The period of stagnation is rarely sufficient to absolutely precipitate all suspended material.

To require this would in most cases be equivalent to snppression of hydraulic mining. It is the endeavor of the Commissiou in each case to reduce the escape to a minimum, and each case has its own solution. It will be uoticed tbat the Commissioners have had a trusted watchmau in the field and have used every precaution to prevent illegal mining. It will also be noticed that work performed under their direction has beeu the means of permittiug several mines to be operated, by which a large number of people have fouud employment and a considerable increase made in the outpnt of gold. At the same time there is little if any fault found, because of an increase of slickens in the rivers, and this is why the *Democrat* has favored a reduction of expenses in paying the manager and attorney of the Anti-Debris Assoeiation.

Mexico's Mineral Wealth.

The uumber of mines now being worked in Mexico, according to recent data, is at least 5000, with others worked only at intervals and still others whose operations are hardly worthy of mention. If to these are added the large number of abandoued claims, many of which if reopened would yield importaut returns—even greater in some cases than those now in course of development—the total would reach, according to our chief informant, "incredible figures," while new mines are beiug discovered day by day.

The total amount invested iu the silver mines of Mexico is roughly estimated at $800,000,000, of which not more thau one-eighth is American capital, while only an amount equal to one-third of the latter, or $33,000,000, is British capital. The annual yield of Mexican silver and gold collectively is set down at about $40,000,000. The output of copper figures at about $2,500,000 and of coal at $4,000,000. If we include iron, sulphur, marble, clay, mercury, salt, stone aud metalloids, the estimated annual total of mining products would amount to not less than $65,000,000.

THE new schedule of wages for the Carnegie employes at Homestead gives an average for every man aud boy of $2 20 per day. Last year it was $2.24; in 1893, $2.44; aud in 1882, $2.43. Under this new scale heaters and rollers will average from $5.50 to $7 per day, while common labor will not be reduced.

The Mineral Hydrocarbons.

Their History, Geography, Geology, Physical and Chemical Properties and Uses.

NUMBER XVIII.

Written for the MINING AND SCIENTIFIC PRESS and copyrighted 1894, by Henry G. Hanks, F. G. S.

The Buena Vista Petrolcum Company was incorporated in February of this year. The oil fields were iu Tulare county, now Kern; they covered an area of 678 acres.

James M. Kenton of Bear valley, Mariposa county, reported to Hon. Samuel Purdy, owner of these lauds, in which he related having sunk two shallow wells some distanee apart, which filled with maltha in one uight.

On January 4th, seventy cans of maltha were shipped to San Francisco from this district by the Buena Vista Petroleum Company.

In 1860 Leonidas Haskell visited this locality with General Fremont. He found "sulphur and salt springs in abundance, but fresh water was scaree. When wells were sunk for water they almost invariably filled up with mineral tar." He was shown a fissure or crack in the earth, caused by an earthquake the year previous, extending for miles, "which in many places was filled with this same tarry suhstance." "The atmosphere was absolutely impregnated with the offensive odor of bitumen for miles around; and it was a common saying with the coasters runuing from San Francisco to southern ports, that they always knew when they were off San Luis Obispo, as well in foggy weather as in clear, by the smell of tar."

I gathered the following early history of the Kern county asphaltum beds from Mr. John Hambleton, whom I met in Bakersfield in May, 1893:

In or about 1861 he was living in Albuquerque, New Mexico, where he met Lieut. E. F. Beale, U. S. surveyor of California, who had information of oil indications in Tulare county, at a very early period. In 1864 Mr. Hambleton was in California, and met Taller and Choyer, Daniel Woodside and Stephen Bond, who, in prospecting in Tulare county, had met with the petroleum indications referred to by Lieut. Beale. He made arrangements with Bond, who returned with him and revealed the locality. The land had been surveyed in townships ouly. Mr. Hambleton selected that portiou on which the oil indications were the most conspicuous, and made a loeation, which he recorded in Visalia. When tbe land was fiually sectionized he relocated his claim according to the new lines. A company was incorporated with the name "Buena Vista Oil Company," of which Stephen Bond was first president.

Soon after, E. Beuoist, a French chemist, was sent to examiue the claims; his report being favorable, he sank a miner's shaft at a point he considered most favorable. This opening was four feet square and eighteeu feet deep, in which considerable thick maltha collected.

Mr. Hambleton verified the statement made by Mr. Haskell as to the fissure made by the earthquake, and said that in some parts of the oil belt, mineral tar rises iu wells sunk for water, aud elsewhere water is covered by a thin film of oil.

Attention was speeially called to certaiu oil iudications at Mattole, Humboldt county, known for several years to exist at that locality; these indications were emanations of gas and seeping of oil on the surface of the ground. An oil belt was seemingly traced from the Mattole river to beyond Cape Mendocino ou the north. It was supposed to be twenty miles long and fifteen wide.

Mr. J. W. Hendersou, now living at Eureka, having heard these facts stated, made an overland trip to the locality from San Francisco; he prospected for two weeks and returned with two gallons of oil as a sample. Soon after, he became associated with Judge Levi Parsons of San Francisco and Thomas A. Scott of Philadelphia. The land being unsurveyed, it was located and held by occupation, pending action by the Land Office.

The Petroleum Oil Works of Santa Cruz had an office, 204 Montgomery street, San Francisco.

1865.—In 1865 the Point Arenas Petroleum Oil and Coal Company had au office in Government House, San Francisco. During the year interest in petroleum in Californuia had increased, until it became an excitement. There was much activity displayed in several sections of the State, mainly in Colusa, Coutra Costa, Humboldt, Los Angeles, Santa Clara and Ventura counties. An opinion prevailed that extensive deposits of petroleum could not exist in the absence of coal beds. This judgment was based ou superficial examinations and the question frequently asked, Who knows that true coal does uot exist below the cretaceous aud tertiary? remained unanswered.

Prof. Wm. P. Blake read a paper before the California Academy of Sciences Feb. 6, referring to the Buena Vista deposits as a new discovery.

Prospecting continued until numerous oil companies were incorporated, and forty or fifty wells were started, mostly in Humboldt county. A tabular statement was published, giviug the uumber of oil companies at seventy, having a collective capital of $50,000,000. Prospecting companies were formed from one end of the State to the other, including

several eastern incorporations, which began to explore in the counties of Santa Barbara, San Luis Obispo and Ventura.

The following are the counties in which operations were most active during this year:

Colusa County.—The oil district in this county was called the "Bear River petroleum district." It was at a locality about a quarter of a mile below Simmons', now Wilber, mineral springs. There were at least twelve companies organized to sink for oil. None met with material success, and during a recent visit to the locality I found no remaining evidence of former workings. Rowe & Fleeson sank a well one mile below Simmons' springs, and the "Antelope Valley and Pioneer Oil Company" commenced operations for the second time.

Contra Costa County.—There was an oil excitement in this county. The "San Pablo Petroleum Company" operated one mile from San Pablo, and a well was sunk in Marsh canyon, southeast of Mount Diablo.

Humboldt County.—Operations of considerable magnitude were undertaken in this county, and there seems to have been sufficient encouragement to warrant it, if published accounts can be relied upon. The principal locality was on Mattole river. Thirty-three companies operated, of which the following were the most prominent and active: Buckeye, Brown & Knowles, Comet, Humboldt Oil Company, Irwin Davis, Mattole Creek Petroleum Company, North Fork Oil Company, Paragon Petroleum Company, Sacramento, and Yosemite.

In the spring, the oil lands of Humboldt county having been surveyed by the Government, Mr. J. W. Henderson and associates purchased 15,000 acres and commenced operations under the name "Joel Flat Company." The usual exaggerated statements were published, which added fuel to the excitement; for example, "Nothing but lack of facilities for transportation prevents large quantities of crude petroleum oil from coming to this market instead of the driblets of a few barrels at a time which we are now receiving." It was also stated that one dollar per gallon was eagerly offered for crude Mattole oil. If it had been quoted at two dollars per barrel it would have been nearer to the real value. It was also widely published that 191 barrels of crude petroleum of 40 gallons each were the product of the Mattole district in October. The following phenomenon is also recorded: On the 3d of August, at the Mattole well of the North Fork Oil Company, a gush of oil rose several feet above the opening. It soon fell, but left the well brim full. The next day the well was pumped out and the same was repeated, which was also the case on the nith and sixth days. Thirty barrels of the oil were shipped to San Francisco. "Six 20-gallon casks of the oil from the Mattole Oil Company was the first shipment of California mineral oil received at San Francisco from the north." Mattole river and the town of Petrolia lie near the sea coast, and about ten miles south of Cape Mendocino. A large oil spring was also said to have been discovered near big head of Mad river. These statements are gleaned from newspapers published at the time. While it is probably true that the accounts were rose-tinted, it is also quite certain that there was real encouragement and that prospects obtained were sufficient to prove that there is mineral oil at this locality, which at some other time, when conditions are more favorable, may be found in paying quantity. When the excitement subsided, which it soon did, work was suspended and was not resumed until quite recently.

Los Angeles County.—The San Fernando petroleum and mining district was organized in June, and C. Leaming was elected recorder. The Los Angeles Petroleum Company sank a well by steam power, which on the 28th of April was down 130 feet. The "San Fernando Petroleum and Mining Company" was incorporated.

Mendocino County.—The "Bolinas Petroleum Company" commenced operations in the Arroya Honda and on the Bolinas ranch. Mr. T. C. Cherry, a Pennsylvania oil operator, came to California to establish an oil refinery. He made a favorable report on the property of the Point Areua Oil Company which commenced operation, but met with but little success.

Nevada County.—Oil is said to have been found oozing from the ground at North San Juan.

San Joaquin County.—The Adams well, at the base of Mount Diablo, acquired considerable celebrity. One statement credited this well with the production of six gallons of oil in March, which sold for $1 per gallon. If it produced more, the yield did not continue, for operations soon ceased and the locality was abandoned.

San Mateo County.—Mineral oil was discovered on Bell's ranch, fifteen miles below Halfmoon bay, and at Purissima creek.

Santa Barbara County.—The "Philadelphia and California" and the "Santa Barbara and California" petroleum companies were incorporated.

Santa Clara County.—A well 135 feet deep was sunk at Lexington by some Portuguese who were prospecting for coal. I was there at the time and saw indications of petroleum. A well at Moody gulch began to produce one barrel of good oil per day.

Santa Cruz County.—The Pennsylvania Petroleum Company commenced operations near the seacoast, six miles south of Santa Cruz.

Tulare County.—In May forty cases of crude oil were sent to San Francisco from the "Pacific and San Joaquin Company's" works at Buena Vista—now Kern county.

Ventura County.—It was stated that in the valley of the San Buenaventura hundreds of barrels of black oil (maltha) had run to waste; some was gathered and sent to San Francisco for treatment. In April, Professor B. Silliman wrote a letter to Hon. D. H. Harris, the publication of which had great influence in stimulating the search for and study of California mineral oils. During this year there was an unusual and I fear an unhealthy excitement as to petroleum in California. It was thought that sinking wells in those localities where indications existed, would surely result in flowing wells such as were at that time quite abundant in Pennsylvania and elsewhere.

(To be Continued.)

As to "Horse Power."

I had the misfortune not long since, says "Inspector," to travel through that part of Indiana where the farmers raise sheep and horses and their sons raise what the late Phil Sheridan preferred to Texas as a place of abode. They were doing it just at that time, for it was during the July unpleasantness at Hammond. A man was sitting near me who in appearance reminded one of Alkali Ike and in ready information of a college professor. I at once sized him up as a civil engineer when he made a chance remark about horse power. I happened to say: "Do you suppose half the people who use that term every day know what it means?" He replied: "No, I don't; and what's more, I think it is one of the most indefinite terms with the most impracticable name that has been tolerated in scientific books. Look out in that pasture now. There's a great big Clydesdale that weighs probably 1500 pounds and another little skinny devil over yonder that weighs scant 900 pounds. Don't tell me that that's a proper unit to rate a steam engine on— Auburn? That's my station. Good bye."

I was sorry the fellow left. His accent indicated that he had been raised in Maine and lowered in Indiana: but his brief closing remark—cut off automatically, as it were—set me thinking, and I felt like thinking aloud for awhile. I knew that a horse power was the work required to raise 33,000 pounds one foot in one minute; but I had sometimes forgotten the time element and knew when riding on street cars and watching loaded drays that each horse was at times doing more than that amount of work. But at this particular time I was impressed with the crudeness of the formula that somebody had thrust upon us and which had been retained for lack of ingenuity to invent a term which would mean scientifically the same thing, but which would have a less number of contradictions in nature, or require less averaging up on the part of the unenlightened in order to arrive at an understanding.

Having this subject in mind, the address of President Henry Morton of the Stevens Institute of Technology, to the last year's graduating class, recently brought to my attention, came to me as a very pleasant assistance. President Morton, among a score or so of "engineering fallacies," which formed the subject of his address, mentioned the common error of failing to recognize a horse power as a *rate* of doing work rather than an *amount* of work done. That is, a horse power is the amount of work a horse is supposed to be capable of doing, not only this hour, but the next, and so on for as many hours as a respectable man will keep a horse at work. The equivaleuts are not calculated for jackasses. However, some of them appear to have been at work upon the other side of the question, for Professor Morton mentions several instances in which the hoary old principle of "conservation of energy," and the adage that "things are not what they seem," are ignored with equal adroitness.

Here, for instance, is an engine using liquefied ammonia in the place of steam. It was made to raise 33,000 pounds one foot high. It took ten minutes to do it, but it was easy to convince an ordinary observer that the machine developed one horse power. As a matter of fact it would take ten of them to do it.

The second example under this head I want to put in President Morton's own words, and it is given for illustrating how easily one may be led to disbelieve the evidence of his own knowledge. These are his words:

"I was asked to test a dynamo machine for which the claim was made that it was many times as efficient as the best Brush or Weston dynamos. I suggested that this was not possible because the above named machines had efficiencies of between eighty and ninety per cent as a theoretical maximum. The reply to this led to the following questions and answers:

"Q. How much power does the ordinary Brush are light require?

"A. About one horse power.

"Q. How does a man power compare with a horse power?

"A. As about one-fifth to one-tenth to one.

"Q. If then one man with the dynamo under discussion can run one Brush are light, will not that prove the machine to be from five to ten times as efficient as a Brush dynamo?

"To this I replied that I would like to see it done.

"In due time there came to hand a large flywheel mounted on a frame, with a pulley for belting to the dynamo and a wheel to turn it by.

"All being arranged, it was found that a strong man could in fact keep up an arc light with this apparatus *for about fifty seconds.*"

But not longer.

The origin of the term "horse power" is somewhat interesting. The first uses of steam engines were to drive machinery for which horses had previously been the motive power. It was therefore quite natural that Boulton and Watt in their early experiments with the steam engine should indicate the capacity of their new machines in units of known powers. They knew by observation that the horses employed around London breweries in draying and in the mining districts in hoisting accomplished about the same amount of work in each working day of eight hours. It also appeared that a horse was working to the best advantage when traveling at the rate of two and one-half miles per hour. It was then easy to ascertain from the different classes of work that at this rate of speed a horse could raise a weight of 150 pounds by means of a rope passed over a pulley. In one minute the weight would be raised 220 feet. By a simple calculation this was reduced to a workable unit in terms of one foot and one minute, giving 33,000 pounds as the result. Since the time of Boulton and Watt this has been the generally accepted unit of power in prime movers, though the French *cheval vapeur* is something over 1000 pounds less.

The time limit again comes up in a different way when we say rashly that a horse can lift 33,000 pounds a foot high by means of a rope passed over a pulley. It would certainly require the accessories of smooth track and light running gear to warrant the expectancy that a horse could draw 16½ tons, to say nothing of lifting a dead weight of that amount. In fact his actual hauling capacity is about one-twentieth of this. The fallacy appears here. If the weight could be raised at all it could probably be as easily done in a second as in a minute. The difficulty arises from the introduction of nature in the shape of a horse into mathematical formulæ. If a hen and a half lay an egg and a half in a day and a half, it opens up pleasing possibilities in the way of mathematics to reduce the result to known terms. But nature abhors the sight of half a hen laying a half egg.

Tin Mines of West Australia.

A practical miner who recently visited the tin fields at Green Bushes, West Australia, gives the following account of operations:

"The ground previous to my going there was all held by companies under leases, but in consequence of an amendment in the mining laws enforcing the labor conditions, they were all abandoned and taken up by individual miners, and worked under mineral licenses which cost 10s. each per year. Each license entitles the holder to four chains by four chains of ground. Generally two men amalgamate two claims by paying a fee of 5s. to the registrar. It is mostly shallow sinking, from 8 feet or 9 feet to 20 feet. All the dirt requires to be puddled in puddling machines, and then sluiced in sluice boxes. After that the tin requires to be streamed until it is quite clean and free from sand. It is then dried in a shed on an iron plate over a fire, and then put in canvas bags—about 1 cwt. in a bag. It is then sent to Sydney, through the agency of the bank, to be smelted and sold. There are no smelting works for tin in Western Australia, Adelaide or Melbourne. It costs 25s. per ton to ship the tin to Sydney. All charges included, it costs about £3 15s. per ton to get the tin to Sydney. Seventy per cent is standard tin. At the present time it is worth about £42 per ton in Sydney. It is sold subject to assay value. There are about 100 miners employed on an average on the field, and the produce amounts to from 250 to 300 tons yearly. It is only a small field and has been open for about five years. There is another tin field in the northwest at the Shaw river. It has already produced about 250 tons of tin. The miners on the tin fields generally made fair wages."

"THE CYANIDE PROCESS; ITS PRACTICAL APPLICATION AND ECONOMICAL RESULTS," is the title of Bulletin No. 5 issued by the State Mining Bureau, a pamphlet of 135 pages, written and compiled by Dr. A. Scheidel, E. M., being an account of the methods employed in the application of the cyanide process in extracting gold and silver from ores in all parts of the world. It is a compendium of up-to-date information on this subject and is of practical value, for there is very little theory, the volume being devoted to telling what the process is, what it costs, and how it can be best handled—just such a treatise as a man interested in the matter in any way wants to get. It may be had upon application to the California State Mining Bureau, Pioneer Building, San Francisco, Cal. Non-residents should send 6 cents postage.

Scientific Progress.

Value of Water Power as Source of Energy.

Owners of water privileges are beginning to realize the fact that the value of water power as a sonrce of energy has been greatly enhanced since the introduction of electrical transmission.

Under proper conditions water is the cheapest source of energy known. It only requires to be controlled by dams, flumes and other devices, to regulate the volume of water supplied to the wheel. The running expenses are merely nominal, as the source of energy is supplied by nature and is always at hand, and the water wheel, if properly constructed and properly placed, requires practically no repairs, no skilled attendants and attention. Regulators and governors are now made which render it possible to give as great steadiness to this form of power as the steam engine gives; and by the use of electricity the power can he transmitted long distances with but a fractional loss of energy.

The great improvements in the steam engine during the past quarter of a century necessitated corresponding improvements in the water wheel, and the inventive genius of the water-wheel makers came to the rescue. In 1804 a patent was issued to Benjamin Tyler of New Hampshire for a "wry fly" wheel, which was based on some of the principles of the modern turbine. This wheel was not used, however, and the real history of the turbine dates from the invention of Fourneyron, who installed the first one in France in 1827. This wheel was small, and was tested under a low head of water, but developed surprising capacity. Power is generated first by utilizing the weight of the water, as in the overshot wheel; second, by the impact of the water, as in the modern turbine or the undershot wheel; and third, by a combination of these two, as in the breast wheel. There should also he added to these the reaction or recoil of the water, which is now made use of in the best designed turbines and impact wheels.

The main point of difference in turbines is the manner in which the water is received aud discharged. The water may he received on top of the buckets or on the sides, and the discharge may he outward or side, downward and inward or central. Fourneyron made use of both impact and reaction, and his wheel was of the side or outward discharge type. There are to-day hundreds of thousands of horse-power running to waste in the rivers and waterways of this country, because of their remoteness from industrial centers, and of the open question of economy of long-distance electric transmissions. But it is only a question of a short time when owners of privileges on these streams shall realize very handsome profits by transforming this latent power into electricity by means of water wheels. Even with the present knowledge of electric transmission, most of these water privileges could be used to generate cheap electricity for lighting neighboring towns and operating electric railways.

Hydraulic engineers claim that water power per horse power should cost, on an average, considerably less than steam power, and the Niagara company evidently believe that this is approximately true when it is reported as offering to deliver in Buffalo and adjoining centers electricity generated at its great plant by the water of Niagara, for $15 or less per horse power per year when units of considerable size are called for.

The greatest obstacle which is encountered in the successful operation of water wheels, from an economical point of view, is that there is too often an entire absence of employment of engineering skill in utilizing the power. Many a water power would develop a greater efficiency had it been properly controlled, and had the turbine been selected because of its adaptability to the conditions and been properly set.

When first introduced turbines were used singly. Now, however, they are used either singly or in sets of two or three or more, as expedient, and in batteries of sets; and by the use of iron or steel penstocks and feed pipes the expense of installing has been largely reduced and much greater economy in the use of water secured. The growing demand for large units of power has been satisfied, so that whereas a few years ago a 500-horse power turbine was almost unheard of, to-day turbines of 5000-horse power have been introduced.

How the Mind is Affected by the Weather.

The psychology of the weather is suggested by Dr. T. D. Crothers as a promising subject for study. He says: "Very few persons recognize the sources of error that come directly from atmospheric conditions on experimenters and observers and others. In my own case I have been amazed at the faulty deductions and misconceptions which were made in damp, foggy weather, or on days in which the air was charged with electricity and thunder storms were impending. What seemed clear to me at these times appeared later to he filled with error. An actuary in a large insurance company is obliged to stop work at such times, finding that he makes so many mistakes which he is only conscious of later that his work is useless. In a large factory from ten to twenty per cent less work is brought out on damp days and days of threatening storm. The superintendent, in receiving orders to be delivered at a certain time, takes this factor into calculation. There is a theory among many persons in the fire insurance business that in states of depressing atmosphere greater carelessness exists and more fires follow. Engineers of railway locomotives have some curious theories of trouble, accidents and increased dangers in such periods, attributing them to the machinery." Dr. Crothers adds that the conviction prevails among many active brain workers in his circle that some very powerful forces coming from what is popularly called the weather, control the work and the success of each one.

Theory of the Tides.

No theory of the tides has been offered which gives entire satisfaction to all scientists, but the one generally accepted is this: The moon, acting alone, would not only raise a wave on the side of the earth nearest to it, by gravitation, but would also draw the earth itself far enough out of its course to leave behind some of the water on the further side; which water would then be raised relatively to the earth's surface, and constitute the second tidal wave. The sun alone would act similarly, although its tide-raising effect is only about two-fifths that of the moon. At new moon the sun and moon pull together and give higher tides than at the first and third quarters, when the sun draws its right angles to the line of the moon's attraction. At full moon, when the sun is on the opposite side of the earth from the moon, virtually the same effect is observed as at new moon. The outer of the solid earth would not at that time he shifted to one side, but the double tide-raising action of the sun would again be super-imposed on that of the moon and give tides on opposite sides as high as those a fortnight before.

AN AERIAL WIRE ROPEWAY on the Bleichert system has been erected at the gold mine on the Joe's Luck and Bon Accord Company, near Barberton, East Africa. The horizontal distance from the mine to the mill is 2,584.59 yards, the total length of the ropeway itself being 2,701,286 yards. The total fall of the line is 1,586.31 feet, the steepest gradient being 53 per cent, and the longest span being 813.67 feet. The transport capacity of the line, as fixed by the company is 42 tons of quartz per day, with a hauling rope speed of 295.2 feet per minute.

Manufacture of Circular Saws.

Circular saws are now made from cast steel, specially manufactured for the purpose, the metal being cast in ingots of various sizes, depending on the size of the saw required. When the manufacture of a saw is commenced one of these ingots is placed in a large furnace, brought to the desired heat, and while hot passed through powerful rolls, which gradually reduce it to the required thickness. The plate is then centered and scribed round to mark the shape of the circle, and passed to the shearer, who cuts it into a circular shape; the center hole is then bored.

It is next handed over to the toother, who punches or flays out the teeth round the edge (this leaves the proper shape of the teeth standing up prominently); they are afterward roughly filed or ground with emery wheels to take off the burr caused by the heating.

The rough saw is now again heated in a large furnace, something like a baker's oven, until it becomes of a bright red color. It is then taken out, and while hot plunged in a bath of sperm oil, which renders it hard and brittle. After being withdrawn from the bath the oil is partly cleaned off and it is returned to the furnace, where it is allowed to remain until the remainder of the oil has been burned off, this process giving the saw the required temper and rendering it tough. When the tempering process is completed the plate is allowed to cool, and then taken in hand by the hammerman, and hammered on a steel-faced anvil until it becomes straight.

The saw is next ground by being caused to revolve in a perpendicular position between two large grindstones, which themselves also revolve in a contrary directiou; it is afterwards polished with emery ou a large revolving disk, and once more passes into the hands of the hammer-men, who strike it with smooth-faced hammers on an anvil, as before, until it is absolutely straight and true and has acquired the proper tension which allows for expansion while the saw is revolving at work. The teeth are now set, to allow for clearance when at work sawing timber, the teeth being slightly bent alternately to the right and left. The saws are afterward sharpened by being filed on front and top of teeth, this operation completing their manufacture.

TESTS have recently been made to determine the loss of heat from steam pipes due to radiation, three distinct conditions being observed, namely, bare pipes, pipes covered with one inch of composition, and pipes covered with one inch of composition and three layers of hair felt, each half an inch in thickness. The steam pressure used was from forty-five to sixty pounds, and the results showed that with one inch of composition out of a possible loss of 100 per cent 83¼ per cent was saved, and with the extra felt covering 8¼ per cent additional was saved. It is stated that if one pound of coal is required to evaporate eight pounds of water into steam at sixty pounds pressure then six and one-half hundredweight of coal would be needed every year to make good the loss of heat for every square foot of uncovered steam pipe.

ON the three hours' trial trip of the English torpedo boat destroyer Ferret, the wonderful speed of 27.51 knots is said to have been developed. This is nearly equal to 31.7 miles per hour, which is higher than the average speed of many express traius. The Ferret is 194 feet long and 19 feet 3 inches beam, with a draught of 5 feet, her displacement being 220 tons. The engines are of the triple expansion type, the cylinders being 19.29, and 43 inches by 18 inches stroke.

A LITTLE STEAMER of a hundred tons is at present being constructed at Argenteuil, according to the invention of M. Bazin, which consists of rolliug the ship over the water instead of forcing it through as at present. To this end a number of enormous copper cylinders are fixed to the vessel, the speed attained depending on the speed of the copper cylinders, and it is computed that thirty-one knots an hour can be easily made. The steering is done by a kind of hydraulic pump, and an advantage claimed is that no way is lost in altering the course. It is hoped that the vessel will be built without loss of time. The trial trip will be made between Dieppe and Newhaven.

Bells.

Bell making is one of the great industries in this country, yet how seldom we hear of it. Foreign countries recognize that our bells are superior in tone to any other make, and even the Japanese are sending orders to this country for bells. The Japanese have long been regarded as famous bell makers, but they do not hesitate to apply to American manufacturers when they find it to their advantage to do so. There is grim humor in the fact that the fire-alarm bells to be used in Tokio have been ordered of a manufacturing firm in Jersey City.

The largest bell in America is in the cathedral of Montreal, and it weighs 28,000 pounds. The bell iu the public building at Philadelphia is to weigh between 20,000 and 25,000 pounds. There is a bell at Erfurt, Germany, cast in 1479, and one in Notre Dame, Paris, cast in 1860, each weighing 30,000 pounds. The great Chinese bell at Pekin weighs 120,000 pouuds, is 14 feet high and 12 feet in diameter. By the way, the Chinese used to make their bells nearly square in shape. The largest bell is, of course, that in the Kremlin at Moscow. It is over 19 feet in height and measures nearly 23 feet across the mouth. Its thickness at the point where the clapper would strike is 23 inches; the cost of manufacturing this work of art was about $300,000.

Cost to Make Steel Rails.

A writer in the *Iron and Coal Trades Review* says: "I believe I am not betraying any secret when I state that at the present range of prices for raw materials, and at the existing price for American labor, Mr. Carnegie can manufacture steel rails for a good deal under $20 per ton. He does not, however, find it necessary to sell at that price. Indeed, a number of the leading buyers in the United States are not much concerned to have prices cut very low. Importaut railway corporations, for instance, prefer to feed the works on their several systems, and if those works cannot execute the order at one price they must just quote another. Hence the firm that cuts prices is not always the most successful."

IF Congressman Livingston can secure enough votes there will be no more "waste of powder" for informing people in the neighborhood of the various posts of the Army that "the sun has risen," or "it's sundown." He objected to a clause in the Army Appropriation bill a few days ago providing for "$20,000 for firing the morning and evening gun at military posts" as an unnecessary waste of powder. "My question is," he said, "What is the practicability of it? What is the advantage of it either to the country or to the Army? If the Lord says when the sun shall go down, I want to know how much advantage this gun is to the country?"

A SCOTCH ENGINEER writes that the white light for safety signal on railways is being replaced by greeu; this is a precautionary measure to avoid the risk rising from the possibility of the red glass of danger signals being broken or blown out aud thus the light being mistaken for a white one, which, under the former system, would have meaut a probable collision. The North British railway, of Scotland, is said to be spending $85,000 iu making this change from white to green, so it is evident that a strong feeliug exists concerniug the dauger of the old system.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

El Dorado.

A HORSESHOE BEND FOR LUCK.—Placerville *Democrat:* The Linden Gold Mining Company is doing a slugging business. Its great gravel mine on Cedar Ravine takes in a crooked channel, forming a labyrinth of loops and horseshoe bends. Through it as a basis for future workings, a tunnel has been run between three and four thousand feet. It has confirmed the favorable opinions of mining experts and been full of encouraging surprises. The latest of them within the last two weeks, was twelve pounds and ten ounces of slug gold, from a run of five days.

Mariposa.

AMONG THE MINES.—*Gazette:* New mining sales are reported from different parts of the county. In the Coulterville district there is greater interest manifested in securing mines than on this side, and several quite important deals have been made recently. Capt. A. H. Ward has purchased the Williams & Morris mine, and is busy developing his group, most of which have been partially tested.

The Virginia mine, which a few years ago was successfully worked, has also changed hands.

Work on the Red Cloud progresses steadily, and before the spring is over some good results are expected from this well-known mine. The superintendent, Mr. Whitcomb, is managing carefully and is confident of success.

New machinery is being put in at the Tyro mine, and work will soon commence.

An important deal in the Whitlock district has just been consummated. J. J. Ellingham has bonded the Farmer's Hope mine and mill to the members of the old Enterprise Mining company. The Enterprise will be recalled as the Madera county mine which yielded $16,000 per week in its palmy days, but has now been worked out. The new company has taken possession of the Farmer's Hope and will at once proceed to test this promising property.

The Sierra Butte company is pushing work steadily at the Whitlock mine, both on the new mill and the mine, and before many months will be taking out the yellow metal in large quantities.

The abundant rains have set the placer miners to work and in every gulch and on every hillside around Mariposa men may be seen ground sluicing and panning and the experienced workers are securing good results.

Mono.

Bodie *Miner:* Work has started up at Green Creek again. The men are engaged in putting a new foundation under the receiver, and digging a long trench for the permanent draining of water-wheel and dynamo foundation work in the power-house. The capacity of the Green Creek reservoir will be about nineteen and a half million gallons.

In the Bodie the south drifts twenty feet above No. 1 west crosscut 400 level was extended fourteen feet; face in porphyry with a small seam of ore. North drift from winze twenty-two feet below the main north drift 300 level was extended eleven feet. The ore in the face is from twelve to fourteen inches wide and of very good grade. East crosscut from Burgess winze level fifty feet below the 200 level was extended eight feet; face in porphyry. Hoisted to the surface thirteen tons of ore estimated at $40 per ton.

Nevada.

RICH ORE.—Thomas & Co., lessees of the New York Consolidated mine on Mosquito creek, have out on their dump thirteen tons of quartz that yield, over $40 per ton, says the *Transcript.* The rock is worked at Maltman & Thompson's reduction works, near Grass Valley, being crushed dry and then treated by the chlorination process. The Niagara mine, which adjoins the New York Consolidated, is being worked and the prospects are very encouraging. A two-foot ledge has been struck and it is improving in appearance as the shaft gets deeper.

Shasta.

Press: The Iron Mountain sale is the all-absorbing topic in Shasta, and bets are about even whether its on or off. The last expert on the ground, a Mr. Hill, from the Rio Tinto of Spain, pronounces it more extensive than that famous mine, while the ores of Iron Mountain carry ten times the value in gold and silver, making it the most valuable copper, gold and silver mine in the world. Mr. Hill is an up-to-date metallurgist, and proposes to use the late improved pyritic processes of smelting.

In the French Gulch district, the Lowdon mill is running on custom ore. The Ellery claim continues to improve with development work. Prof. Morton reports eighteen men at work on the Myers property, with a fine showing of high-grade ore. The Washington people are again talking of a sale to a New York syndicate.

James Sallee is going to put on a steam pump and hoist on the Upper Springs. Mr. Samonai at the Gem mill is working some ore and testing the new concentrators. The latter seem to be wholly an experiment, the inventors trying to adopt them to the Shasta county ores.

Siskiyou.

GENERAL MINING NOTES.—*Journal:* Austin & Co., of the Greenhorn Blue Gravel Mine, about a mile south of Yreka, took out a nugget weighing $55 last week, and are working very rich ground at present. Owing to snow not melting much in the mountains, on account of the cool nights, the water supply is rather limited, and there is no water coming down from the creek. There is plenty to come however, when the weather is warm or warm rains occur, as the Humbug and Deadwood range is covered with from four to six feet of snow.

The hydraulic miners at Quartz Valley, Oro Fino, Salmon River, Cottonwood, Humbug, South Fork of Scott River and all along the Klamath river are doing good work, in piping the banks with giants, with expectation of doing still better when the weather becomes warmer, to melt the snow faster. The water supply for hydraulic mining this season it likely to last longer next summer than any year yet known, as the snow seems to have all bunched into the districts above 4,000 feet altitude, just where it is needed for the greatest benefit for mining purposes. The miners at Hawkinsville are all doing well this season, with better times ahead, and there is an abundance of snow to supply Canal and Long Gulches with an abundant supply of water for a long time, and the same may be said of Humbug Gulch coming down on Yreka Flats, and Greenhorn Creek, a little south of Yreka.

The recent heavy rain has afforded an abundance of water for mining, to permit continuance of operations right along full handed, in the various hydraulic and placer mining claims, and also plenty of water power to start quartz mills. River mining will probably be suspended, as the streams are too high, and most of the claims are filled up with water, to require pulling out the apparatus, or not advisable to pump out before spring until the danger of heavy freshets is over.

Jillson & Co. intend putting up a new quartz mill of five stamps at their blue gravel mine near Henely, for crushing the blue cement and gravel taken out, as the best means of securing the gold it contains. They have heretofore been using an arrastra, which does not break up the gravel to good advantage.

NEVADA.

Esmeralda.

A GOOD MINING DISTRICT.—Advices from the Silver Star mining district are to the effect that everything there looks bright and prosperous. The little mill recently erected is continually at work, and there is ore enough on the dumps to keep it running for the next year. The Hardscrabble mine keeps to the front. The owner is reported to have refused $120,000 for it. Other mines in the district are yielding good ore.

A BRIGHT OUTLOOK—Frank Robb, who has been engaged in erecting a mill building at the new mining district in Esmeralda county, is very enthusiastic over the outlook in the district and says it surpasses anything in the mining line he has ever seen. The principal mine is owned by Ed Brown, in which, he says, there is $150,000 in sight and no sign of a let-up to the ledge. The workings are not deep, the main shaft being down about 190 feet. Rich ore was taken out from the grass roots to the bottom. Good ore is being taken from several other claims in the district, and Mr. Robb thinks that all indications Silver Star District is destined to create a big stir.

Storey.

In the Savage on the 1000 level they continue to extract ore from the sill floor in the north lateral drift from the east drift up to the 9th floor. On the 1050 level in the south drift from the east drift thirty feet from the south ore stopes they continue to extract ore of fair grade. They are still stoping ore from the bottom of the winze in the south drift. They have drifted north fourteen feet on the streak of ore mentioned in the last weekly report as encountered in the east crosscut from the south drift.

ARIZONA.

FOREMAN ALMOST CRAZY.—*Star:* A Mexican from the Mineral Group, a copper property near San Xavier, owned by Messrs. Hughes and Banes, says that a big and wonderfully rich lead of copper ores had been struck that day in the mines, and that the foreman had about gone crazy over the rich discovery. This property was bonded some time ago by the International Copper Company of El Paso, who have at this present time forty men at work on the mines. Several large shipments of ore have already been made to Texas.

The Mohawk mine at Mammoth will be in full operation, mill and all, by the 1st of June. Superintendent Bailey is letting a contract for a drift of 275 feet along the ore. This will connect the two shafts and get air supply. A total of three miles of piping will connect the mill with the San Pedro river. Pumping to the mill and various means of conveying the ore from the mine to the river have been carefully calculated on, and pumping is considered the most economical. A pump that will be the pioneer of its kind will be put in. It will throw water stronger than any other make, if it keeps up the expectations.

MEXICO.

The old duty on lead ores was a cent and a half a pound; the present duty is three-fourths of a cent a pound. There has been a very marked increase in the shipment of ores from Mexico, but not, as might be supposed, from the reduction of duty in the ores. Heretofore the mine owners have hoped that some legislation favorable to silver would occur, and for this they have vainly hoped and waited. Now they see they have no prospects in that regard, so they ship the ores they have, and make what they can with silver as it is. The ready money is needed, and if not what they can obtain is accepted. Mexican dollars are now 49 in Nogales, so that goods there were never marked higher than they are at present.

OREGON.

JOSEPHINE CO.—Major Newell has hung up his gold-pumping boat for awhile and gone to Portland where he will negotiate for a larger boiler and more powerful pumping apparatus. The Major is still confident of the success of his scheme.

WASHINGTON.

The following is furnished by the secretary of the Tacoma Chamber of Commerce:

REPORT OF TACOMA SMELTER FOR THE MONTH OF DECEMBER, 1894.

Number of men employed	64
Pay roll	$5,180 36
Wood choppers and wood haulers	468 00

OKLAHOMA.

A Guthrie dispatch says: Hundreds of prospectors are swarming into the Wichita mountains, in the Kiowa and Comanche Indian reservation, caused by the discovery of deposits of gold and silver. Troops have been ordered from Fort Reno to eject them, and serious trouble is looked for, as the prospectors declare they have a right in the mountains under the mining laws, and will not leave. Many samples of ore have been brought out for assay.

Coast Industrial Notes.

—The Eureka Electric Storage Battery Co. has removed to commodious quarters at 645 Mission St.

—Southern California is now daily producing over seventeen hundred barrels of petroleum.

—A Tacoma, Wash., dispatch says all the logging camps will start up in that State within a week.

—The Portland, Or., 5 per cent water bonds have been sold to E. & S. Ellis of this city at a premium of $11,000.

—The city of San Diego has offered $600,000 for the plant of the San Diego Water Company. The offer has been declined.

—During December the Everett, Wash., smelter shipped bullion to the amount of $107,000. The product for the month included 3,000 ounces of gold, 60,000 ounces of silver and 500,000 pounds of lead. It has since closed down.

—There are over a thousand laborers working with scrapers and shovels on the Yaqui canal, Sonora, Mexico, besides those employed on the dredge. The canal is expected to be finished by April, and the dam will be constructed in May.

—The steamer Australia is being cleaned and painted at the hydraulic dock of the Union Iron Works. She will be succeeded by the steamer State of California, which will have her broken shaft removed and replaced and other repairs made.

—At the recent sale of the Hudson Bay Company in London the highest price brought was 35s a seal skin the average was 30s. There is a blue lot of sealing men in Alaska. The news was a complete surprise, for never have skins sold so low in the history of the Bering sea industry.

—Lieut. Dorn and Engineer Mallison leave New York next Monday via Panama in charge of 70 petty officers and sailors which will form the nucleus of the cruiser Olympia's company. The Union Iron Works will complete the vessel as fast as the required material is furnished. She will be the flagship of the Pacific station; it is thought Capt. Reed will have command.

—Captain J. A. Mellon is having two boats built here which he will take by rail to Green River, Wyo., in April, and, assisted by river men, will descend the Colorado river to Yuma and the Gulf of California. Captain Mellon has been running steamers on the Colorado river thirty-two years. He is a resident of Yuma, Ariz., and proposes to make the trip of 3000 miles in seventeen days.

—D. Freeman, president of the Los Angeles Chamber of Commerce, the past year writes: "We are still suffering from underproduction in the very necessities of life. When it takes a train of cars nearly a mile long to bring into this State the eggs that the enterprising hens of Kansas and Iowa lay for us, and when we import annually over 4,000 carloads of bacon, poultry, dried fruits and other products, to the value of $8,000,000, that could be raised here, let no one croak about overdoing things in this country."

—In Orange Co. the Union Oil Company has begun sinking wells five miles north of Fullerton and adjoining the Puente wells on the west. The company has over eleven hundred acres of land east of the Puente wells, which it purchased from the Stearns Ranchos Company, a year ago. The Puente Oil Company is securing the right-of-way for its pipe line to Fullerton, and it is the intention of the Santa Fe Company to make this town the oiling station for their engines, as that is the only point on their line that oil can be piped to.

—During last summer $12,000 worth of new machinery and apparatus has been purchased and installed at the Throop Polytechnic Institute, Pasadena. This includes additions to chemical, physical, electrical, and biological equipments, a new steam plant, complete pattern shop outfit, a complete machine shop outfit, and a Sloyd school equipment. The total value of the equipment, at present, amounts to about $100,000. A class has been organized and is now pursuing a course of training in Sloyd work. A department of accounts, stenography and type-writing provides business training. The department of art offers excellent facilities in both painting and drawing. There have been valuable accessions to the libraries located in the several departments.

—The Snoqualmie Falls Electric Power Co., State of Washington, has acquired 350 acres of land on both sides of the Snoqualmie river, and an option on as much more land adjoining. The theoretical energy of the falls is 51,607-horse power. The plans of the company are to develop and deliver by electrical transmission, power for factories, lighting, heating, etc. A contract has been arranged with the Union Electric Company of Seattle to have the company furnish them with its power entirely; the price charged per horse power being $30. The capital stock is 20,000 shares of $100.

—Nearly 100 new buildings are to be built this year at the Presidio, to be occupied as barracks, built of brick and stone and inclosed by a stone wall. They represent an aggregate cost of about $300,000. Seven brick stables, costing about $110,000, will also be built. An administration building to cost $50,000, and forty brick and stone buildings, to cost in the aggregate $200,000, a stone wall to include a large part of the reservation, the improvement of the grounds and other minor changes, aggregate up to $1,000,000 in total. The contract for one barrack building, to cost $40,000 has been awarded. The second building is to be finished by next July. The department is now receiving bids for the stone wall and will soon receive bids for the work of filling in the parade ground, macadamizing etc.

—The rivers of the Pacific coast formerly contained no shad, but in 1876 the fish commission carried a quantity of shad fry across the country and placed them in the Columbia and other rivers. The fish propagated to such an extent that in 1892 the number of shad caught on the coast of California was 526,424, and 212,350 more was taken in the Columbia river. The total catch of shad for 1892 on the Pacific coast was in excess of the number caught off Connecticut, Rhode Island and Massachusetts, and it nearly equaled the catch of South Carolina. Though the total catch of shad on the Pacific coast is at present very small in comparison with that of the Atlantic seaboard, their rapid multiplication since they were placed in the rivers of California, Oregon and Washington renders it not unlikely that in the near future they may be more plentiful on the Pacific than on the Atlantic coast. This is one of the most interesting results so far recorded of the work of the government fish commission.

The Geographical Society of the Pacific.

The annual meeting and election of this society took place at the rooms, Mercantile Library building, on the 15th inst. For 1895 the following officers were elected:

Directors—Prof. George Davidson, U. S. Coast Survey; Charles L. Taylor, Harry Durbrow, John Partridge, E. J. Bowen, Louis L. Nelson, John Dolbeer.

Councillors—Hon. Ralph C. Harrison, Mark Sheldon, William Hood, Hon. Charles Goodall, James F. Houghton, Gustave Niebaum, Hon. George C. Perkins, Henry Lund, Irving M. Scott, Hon. Jeremiah Lynch, Adolph Sutro, F. Stevens Cook, M. D.

The directors selected the following officers: President, Geo. Davidson, Sc. D., Ph. D.; vice-presidents, Hon. Ralph C. Harrison, Col. Chas. L. Taylor, Irving M. Scott; treasurer, Harry Durbrow; corresponding secretary, Hon. Jeremiah Lynch; recording secretary, John Partridge; assistant secretary, T. F. Trenor, A. M.

The report of the council showed the work done and the papers read in 1894. Hon. Jeremiah Lynch's paper on the late discoveries in Egypt, expected in November, was assigned to a later date. Professor Schaeberle, of the Lick Observatory, will be invited to make his address this month.

The library has largely increased during the past year. Many handsome volumes have been presented, and maps have been added, suitable for the lecture room. The conference held by the society last May at the Midwinter Fair attracted general attention from Eastern and European geographers. A number of the papers then sent in, and which there was not time to read, will be given at future meetings, by consent of the authors.

A WACTHMAKER in Geneva proposes to make a chronometer which will speak, instead of ringing, the time, when the button is pressed. He has devoted a great deal of patient study to his invention, the speaking process being produced by means of a small revolving phonographic plate in which presses a small piece of steel. The vibrations resulting give rise to words denoting the exact time.

Incompetent Steamship Inspection.

The *American Machinist* says the steamer Kewecnaw, lost with all hands in a gale, was one of the vessels built on the Lakes which on first arriving at San Francisco. was a nine-days' wonder to the engineers and seamen of the coast.

The boilers, without proper end mau and hand holes for inspection and cleaning, had been driven at high pressure on salt water during the voyage around the Horn, and in consequence were completely coated internally with a heavy non-conducting scale, aud several of the corrugated furnaces had collapsed by reason of overheating.

Cast-iron engine columns, cracked completely across, were patched with slips of boiler plate tacked on by a few ½-inch or ⅝-inch tap bolts, and those who saw the machinery were forced to wonder what kept the entire plant from lifting bodily skyward when steam was turned on. The oiling gear was *tied* to the rods, links, etc., by pieces of wire and *common twine*, and bore the appearance of having been culled from some scrap heap, the leads of piping being so small that they must have gummed up completely after a day or two of running.

The hulls, built of light scantlings, were continually undergoing repairs; rudder posts and stern framing broken or wrenched while voyaging in the ordinary weather of the Pacific, where what would be considered on the Atlantic seaboard as a moderate blow, is looked upon as a serious hurricane.

From time to time criticism of the men and methods employed in the inspection of steam vessels appears in various quarters, but there has been no concerted action taken to impress upon officials their responsibility for loss of life at sea where this is due to neglect of proper precautions on the part of builders, owners or commanders.

Unless steamship inspectors are men of integrity, experience and skill, the government supervision of vessels becomes a farce, for few of those financially interested will go to the expense to improve machinery or hulls, so long as the local inspector will allow inferior constructions to pass muster.

The notion that captains or engineers will report matters if the ship is unseaworthy or the engines defective is held only by those who are unacquainted with steamboating. In a great majority of cases, the employe of a company, who should condemn the corporation's holdings, would quickly find himself without a berth, whatever might be the truth of his report.

If the traveling public is to be protected, instead of the political generals and ward heelers too often in charge of inspection, men of acknowledged ability in their calling should be substituted. A radical change is absolutely necessary, for the present state of affairs is a national disgrace. Steamers totally unseaworthy, half manned and half equipped are allowed to put to sea by the political hacks, who, by reason of ability to answer set questions in amateur mechanics, are furnished a license by the civil service boards to pass upon matters involving daily risks to thousands of human lives.

The Explorers' and Assayers' Companion.

A Third Edition of Selected Portions of the "Explorers', Miners' and Metallurgists' Companion."

By J. S. PHILLIPS, M. E.

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying and Metallurgy.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay has been kept as free from formulæ as possible. The work is written for practical men, and all the explanations and discriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

Price $3.00 postpaid. Sold by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco

OUR PIPE IS FOR SALE.

For Hydraulic Mining and Irrigation Purposes Our Sheet Iron and Sheet Steel Riveted Water Pipe Is Unexcelled.

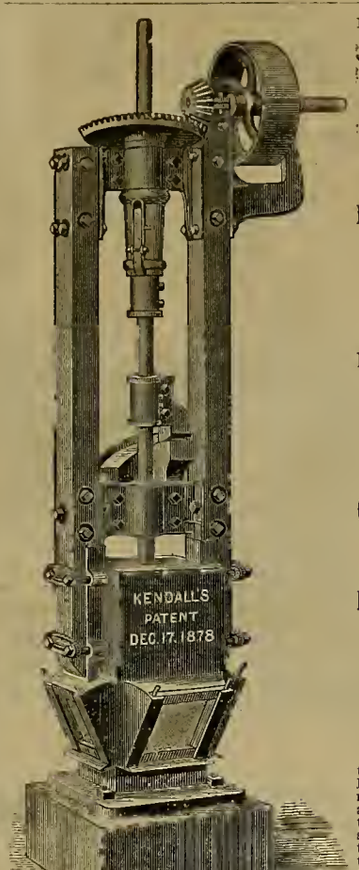
We Have Also a Large Line of the MATHESON JOINT (Lap-Welded) Pipe, for Which We Are Agents.

Our Prices Are Low; Our Pipe Is Superior, and We Want More Business. May We Quote You Prices?

PIPE FITTINGS, TOO.

RISDON IRON WORKS,

SAN FRANCISCO, CAL.



L. C. MARSHUTZ. T. G. CANTRELL.

NATIONAL IRON WORKS,

N. W. Cor. Main & Howard Sts., San Francisco.

MANUFACTURERS OF

STATIONARY AND COMPOUND

ENGINES,

FLOUR, SUGAR, SAW AND QUARTZ MILL

MACHINERY.

AMALGAMATING MACHINES.

CASTINGS AND FORGINGS

OF EVERY DESCRIPTION.

All work tested and guaranteed.

IMPROVED PORTABLE HOISTING ENGINES.

Sole Manufacturers of

Kendall's Patent Quartz Mills.

Having renewed our contract on more advantageous terms with Mr. S. Kendall for the manufacture of his Patent Quartz Mill, we are enabled to offer these mills at **Greatly Reduced Prices.** Having made and sold these mills for the past 14 years, we know their merits, and know that they have given perfect satisfaction to purchasers, as numbers of commendatory testimonials prove. We feel confident, therefore, that at the prices we are now prepared to offer them, there is placed within the reach or all a light, cheap and durable mill that will do all that is claimed for it and give entire satisfaction.

MARSHUTZ & CANTRELL.

FRANCIS SMITH & CO.,

—MANUFACTURERS OF—

SHEET IRON & STEEL PIPE

FOR TOWN WATER WORKS.

Hydraulic, Irrigation and Power Plants, Well Pipe, Etc., all sizes.

130 BEALE STREET, SAN FRANCISCO, CAL.

Iron cut, punched and formed, for making pipe on ground where required. All kinds of Tools supplied for making Pipe. Estimates given when required. Are prepared for coating all sizes of Pipes with a composition of Coal Tar and Asphaltum.

Professional Cards.

A. H. RICKETTS, Attorney-at-Law, Mining Patents and matters before the Land Department a Specialty. Crocker Building, Rooms 201, 202 and 203, San Francisco.

WM. GILBERT, B. S., Manager. PRACTICAL ENGINEERING SCHOOL, 205 Goodnough B'ld'g, Portland, Or. Civil, Electrical, Steam, Mining, Assaying. Full charge of plant taught. Circular.

The Evans Assay Office.

W. N. JEHU, - - - - Proprietor. Successor to Jehu & Ogden.

628 Montgomery Street, San Francisco. Rooms 46 and 47 Montgomery Block.

Ore Assays, Analyses of Minerals, Metals and their Alloys, Etc.

LESSONS GIVEN IN ASSAYING.

School of Practical, Civil, Mechanical, Electrical and Mining Engineering.

Surveying, Architecture, Drawing and Assaying. 723 Market St., San Francisco, Cal. OPEN ALL YEAR. A. VAN DER NAILLEN, President. Assaying of Ores, $25; Bullion and Chlorination Assay, $25; Blowpipe Assay, $10. Full Course of Assaying, $50. Established 1864. Send for Circular.

Almarin B. Paul, M. E.,

Mining Operator,

ROOM 5, CROCKER BUILDING. Cor. Market and Montgomery Sts., San Francisco.

Will give attention to the sale of and reporting on RELIABLE Mining Properties, or the procuring of suitable Machinery for Interest in Developed Mines.

Plans and Estimates made for IMPROVED CYANIDE PROCESS PLANTS, and competent instruction for working the same on a large, practical scale.

Nevada Metallurgical Works,

No. 23 Stevenson Street, Near First and Market Sts., San Francisco.

C. A. LUCKHARDT, Manager. Established 1869.

ORES WORKED BY ANY PROCESS. Ores Sampled.

ASSAYING IN ALL ITS BRANCHES. Assays of Ores, Minerals, Waters, Etc.

WORKING TESTS (PRACTICAL) MADE.

PLANS AND SPECIFICATIONS furnished for the most suitable process for working ores.

SPECIAL ATTENTION paid to examinations of mines; plans and reports furnished.

C. A. Luckhardt & Co.,

(Formerly Huhn & Luckhardt), Mining Engineers and Metallurgists.

Everette's Mining Office.

(Pioneer Mining Geologist's Office of the Pacific Northwest.)

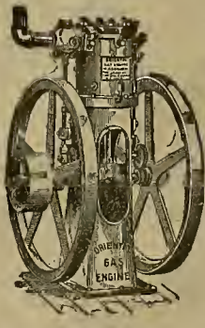
MINING LAW, MINE EXAMINATIONS, METALLURGY, ASSAYING AND ANALYSIS.

"Consulting Associate Mining Attorney at Law."

Will examine and report upon "Title and Exact Value" of Gold, Silver, Lead, Coppor, Coal, Iron, Clay or other Mineral Properties IN ANY PART OF THE WORLD. Any information mining men may desire to know, relative to the MINERAL or COAL resources of the entire Pacific Northwest, will be honestly given.

Dr. Willis E. Everette, 1318 E Street, Tacoma, State of Washington, U. S. A.

The Oriental Gas Engine



IS THE BEST because it combines simplicity of construction with power and economy of space. It can be run with natural or manufactured gas or gasoline at a cost of 20 to 25 cents per horse power per day.

It can be used for pumping purposes, as well as for all purposes where a perfect engine is required. with the advantage of lessening the risk of explosions. No licensed engineer at a high salary needed to operate it.

Send for circulars and prices if a good safe engine is what you need.

The Oriental Launch is Perfection.

M. A. GRAHAM,

Inventor and Manufacturer,

105 Beale Street.....San Francisco.

BACK FILES of the MINING AND SCIENTIFIC PRESS (unbound) can be had for $3 per volume of six months. Per year (two volumes), $5. Inserted in Dewey's patent binder, 50 cents additional per volume.

Electrical Progress.

Electricity on Shipboard.

At the second annual meeting of the Society of Naval Architects in New York, last month, an able and interesting paper on "Electricity on Shipboard" was read. The author, S. Dana Greene, late ensign United States Navy, pointed out the rapid march which has been made during the past decade in the development of electricity on shipboard, and says that this agency has become recognized and standardized so that it can be relied upon for continual and active service. As a result there have been developed for marine work a special type of generating set (engine and dynamo), special appliances (switches, junction boxes, cut-outs, stuffing tubes, water-tight globes and lanterns, etc), special insulation for conductors, special methods of wiring, special forms of searchlights, and special men who may properly be called "marine electricians." These apparatus and appliances differ materially from those in use on shore, and must be used under service conditions entirely dissimilar. Salt water, salt air, steam and the excessive heat of ship boiler and engine rooms, would play havoc in a very short time with the best modern shore insulation, as they have with many of the early ship plants, and if there is any place in the engineering world where the old axiom of "penny wise and pound foolish" should be stamped in large letters, it is on the plans of an electric marine plant.

The uses to which electricity is now being put on board ship are numerous and in naval vessels it has become an absolute necessity, while in freight and passenger steamers and high-class yachts it is also universally applied. Aside from many mechanical uses, electricity as applied in navigational features has become invaluable, prominently so when turned into the searchlight, electric logs, the electric steering compass, means of communication between the various officers and parts of large vessels, signalling and firing circuits, as well as being used as a range or position finder.

Relative to the electric log Ensign Greene points out that the French navy has recently adopted one, the invention of Rear-Admiral Fleuriais. A set of revolving vanes on the log impart, through worm gearing, motion to an ivory disk mounted in the log, and a spring makes contact with metallic plates placed at intervals on the rim of this disk. As this contact takes place, a bell is sounded aboard ship, once for every twenty-four revolutions of the vanes. The intervals between signals is arranged 11 seconds for 8 knots, 8.8 seconds for ten knots, 4.4 seconds for 20 knots, and is, therefore, of sufficient length to prevent error. To indicate fractions of a second, the usual sand-glass has been displaced by a pendulum indicator which beats at intervals of two tenths of a second, and which is started at the moment of taking an observation. A mistake of half a second, with a period of 50 seconds, makes an error of only one-tenth of a knot in the speed of the vessel; if the observation is prolonged, the error is reduced. The apparatus is simple and apparently gives good satisfaction. The log is about 9¾ inches in diameter and is not watertight. Another French invention, by Lieutenant Bersier, French navy, which will probably be introduced aboard ship, is the steering compass. Its object is to keep a ship on her course automatically and without the constant manipulation of the wheel in the hands of the helmsman. The following brief description of the device is taken from a recent technical journal. The electric spark of a Ruhmkorff coil is made to unite a pointer on the circumference of the compass card with either one of two semi-cylindrical, metallic plates, which are electrically insulated from each other and from the side of the compass box of binnacle. The coil is placed a few yards from the compass and is supplied by an alternating current of from two to three amperes. The induced current of the secondary coil reaches the pivot of the compass, through a flexible wire, and passes thence to the aluminum capsule that carries the sapphire, and follows along an aluminum wire or pointer which forms a radius of the north pole of the compass. As the ship deviates to the right or left of her course, the current leaps (through a distance of about an inch) from the pointer to the right or left hand insulated plate in the binnacle, and thence flows through one of two electro magnets, which, in turn, close the circuit, in one direction of rotation or the other, of a small-150 watt motor. The shaft of this motor is keyed to the shaft of the rudder motor, which moves the rudder in the direction required to bring the ship back to her course. It is reported that the compass card is entirely uninjured by the current or spark, and that the device has been tested in squadron practice for two months with complete success.

A HANDY LITTLE DEVICE has been brought out for preventing the waste of current that often goes on in the electric lighting of hotels and large buildings. In hotel bedrooms, cellars and other places where persons are constantly passing in and out and requiring light for only short periods it not infrequently happens that the light is switched on and left burning, sometimes for many hours, to no purpose. The apparatus which makes such waste impossible is a small piece of clock work, by means of which an incandescent lamp is automatically switched off in half an hour, or any prearranged time. It can be included in any ordinary circuit instead of the switch, and at a very moderate cost.

BULBS of incandescent lamps are now blown with artistic designs in relief, thus obviating the use of a shade and increasing the beauty of the lamp.

Highest Bridge in the World.

The highest bridge of any kind in the world is said to be the Leo river viaduct on the Antofagasta Railway, in Bolivia, South America. The place where this highest railway structure has been erected is over the Melo rapids, in the Upper Andes, and is between the two sides of a canyon which is situated 10,000 feet from the level of the Pacific. Counting from the surface of the stream to the level of the rails this celebrated bridge is exactly 636½ feet in height. The length of the principal span is eighty feet, and the distance between abutments (total length of bridge) is 802 feet. The largest column is 314 feet 2 inches long, and the batter of the pier what is known to bridge builders as "one in three." The guage of the road is two feet six inches, and trains cross the bridge at a speed of thirty miles an hour.

20-Stamp Mill for Sale.

In Southern California, a 20-stamp Gold Quartz Mill, with engine, boiler, self-feeders, rock-breaker, etc.

As the premises are adjacent to Railroad, the Mill could be conveniently removed. Can be had at low price for cash. Address: "Quartz Mill," care MINING AND SCIENTIFIC PRESS, San Francisco.

UNITARIAN LITERATURE sent free by the Channing Auxiliary of the First Unitarian Church, cor. Geary and Franklin Sts., San Francisco. Address as above. Mention this paper.

A thoroughly competent Amalgamator wants a position where mine and mill assaying is required. References given. Address Box D, this office.

TUBBS CORDAGE CO.

THE JONES ROCK DRILL

IS THE

Only Successful Hand Power Drilling Machine Ever Invented.

It is strong, durable, reliable, simple, compact, light, easily handled and operated by one man, and will reduce the cost of rock drilling at least Fifty per cent.

Our handsomely illustrated pocket catalogue fully explains the features and workings of the drill. It should be in the hands of every mine owner, leaser, contractor and prospector in the West. *Sent free on application.*

If you are interested in Rock Drilling Correspond with us.

WE CAN SAVE YOU MONEY.

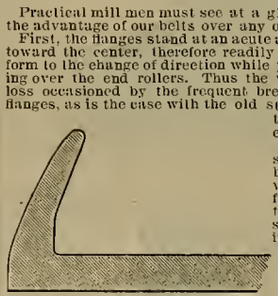
FRANK T. SUTHERLAND, M'g'r Pacific Coast Agency.

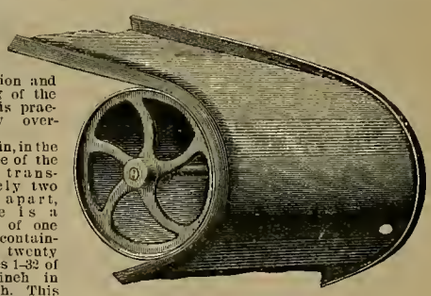
Office and Warerooms: 9 FREMONT St., San Francisco, Cal.

Or, Address the Company at its Denver Office.

Blasdel Improved Concentrating Belt.

We keep in stock belts suitable for the Frue, Triumph, Johnston and Tullock machines, and make all lengths and widths to order.





Practical mill men must see at a glance the advantage of our belts over any other. First, the flanges stand at an acute angle toward the center, therefore readily conform to the change of direction while passing over the end rollers. Thus the vexation and loss occasioned by the frequent breaking of the flanges, as is the case with the old style, is practically overcome.

Again, in the surface of the belt transversely two feet apart, there is a space of one inch, containing twenty rifles 1-32 of an inch in depth. This tends to equalize the pulp and prevents it from banking on the edges, or forming channels. This rifle saves fine sulphurets and quicksilver that would escape with the tailings from a belt with an entirely smooth surface.

Practical Information.

Sighting Big Guns.

Any one who has ever watched the target practice at any of the military points has no doubt been surprised at the way the guns are pointed, so that a shell, although it misses its mark, will drop into the water on the same line with the target.

"How do they get the range so well?" the unsophisticated will ask.

"By a range finder," some soldier or sailor will reply, and then he walks off," leaving the spectator wondering where the range finder is and what it may be.

The range finder is an instrument invented by Lieutenant Fiske, formerly attached to the United States ship San Francisco, and is one of the most complicated of the many pieces of mechanism on board a modern warship. The mass of mechanism is in a box which is about two feet square, and on the top of it are two small but very powerful telescopes at a distance of about a foot and a half apart. These two glasses work on a pivot, and also have an oscillating hinge so that they may be turned in any direction. Both glasses are directed upon one point, and the pivot in turning works upon a cogwheel below. This cogwheel, when turned, starts the machinery to work, and in much less time than it takes to tell about it the machinery indicates how far the target is from the water line of the ship.

The principle is that, as the distance between the two glasses is known and their angle is shown on a dial at the top of the box, the good mathematician can figure out almost instantly how far the center of the triangle is from the ship's side. With Lieutenant Fiske's range finder, however, the mathematician is not needed, for the machine figures out the distance itself, and when the telescopes have been adjusted and the machinery started it is but a moment before the bell rings and the distance is shown on an indicator at the breech of the gun. The range finder is worked by electricity.

It is but one of the many great improvements that have been made in gunnery during the last three years, and it is one of the most valuable. In the old days, when target practice was held, an officer used to stand on the ship's rail with a contrivance which looked like a T-shaped ladder. The rungs of this miniature ladder marked the degrees, and the officer, by holding this instrument and a strong pair of binoculars to his eyes could see how many degrees high or low, or to the right or left of a target, that a shell struck. But this was a great deal of work, and it was not altogether accurate, either. The range finder, though, is positively correct.

Many men have tried to prove that the range finder was not correct in its figures, but a range finder in good working order will solve any problem in its own particular line that may be put to it. A range finder is very rarely used when the distance is under 1000 yards, for any good gunner can guess at the proper sighting for a short distauce.

The American invention is the only good range finder in existence, and the navies of the other nations are speedily adopting it. They have already taken the American torpedoes, breech plugs and other improvemeuts.

Cost of Railroad Cars.

An ordinary flatcar costs to build about $380; a flat bottom coal car costs $475; a gondola drop bottom coal car, $525; a double bottom hopper coke car, $400; a box car, $600; a stock car, $550; a ventilated fruit car, $700; a refrigerator car, $800; a four-wheeled caboose, $550, and an eight-wheeled caboose, $700; a fifty-foot mail and baggage car, $3500; a second-class passenger coach, $4800; a first-class coach, $5500, and a first-class Pullman car costs $15,000.

THE *Engineer's List* says: "A good preparation for preventing tools from rusting is made by the slow melting together of six or eight parts of lard to one of rosin, stirring till cool. This remains semi-fluid, ready to use, the rosin preventing rancidity and supplying an air-tight film. Rubbed on a bright surface ever so thinly it protects and preserves the polish effectually, and it can be wiped off clean if desired, or it may be thinned with coal oil or benzine."

THE meter is 39.375+ inches, the decimeter 3.9375, the centimeter .39375 and the millimeter .039375 of an inch. A fair approximation can be had by calling the millimeter .04 or $\frac{1}{25}$ of an inch and the centimeter .4 of an inch, and by having some number to use as a comparator we get a better idea of the actual sizes, for five millimeters mean very little to us unless we think that it is about $\frac{1}{5}$ of an inch.

AN ENGLISH PAPER contrasts the cost of a steamer of 3500 tons capacity built on the Clyde in December, 1889, with the cost at which such a boat may be purchased from the same builders at the present time. The former price was $157,500 against $107,500 at present. Machinery is the same in both cases—triple expansion, 22, 35 and 59 inches by 39 inches stroke.

A BELGIAN INVENTOR has devised an immense lamp such as has probably never been seen before. The lamp is composed of 3,000 pieces. It is 6 feet high, and measures 7.10 feet, in diameter. It is fed with lard oil, and the consumption is said to be very small, its light being so powerful that one may read by it at a distance of 600 feet.

Market Reports.

The Markets.

SAN FRANCISCO, Jan. 17, 1895.

Silver has been below 60 all the week. Extensive silver shipments are being made from New York and Omaha to Mexico for coinage at the Mexican mints.

Mexican dollars are quoted on the market at regular prices in advance of the value of the bullion contained in them. There is a small charge for mintage at the Mexican mint and a peculiar demand for them for trade with the far east. The owners of the bullion must have figured out the probable profit of the transaction and come to the conclusion that their silver will be worth more, adding all additional expenses, in the form of Mexican dollars than in the uncoined bars. The continuance of the practice must depend upon the profit to be gained, and this in turn upon the relative prices of silver bullion and Mexican dollars.

Omaha and Denver are also shipping refined silver bullion to China. In London the price of silver is dominated by the course of the American supplies. When these have all been pressed for sale the market has dropped away, for China and Japan have not been buying, and the very moderate Indian demand for the metal has been checked by the fall in the currency quotation since the cotton duties were formulated. In the New York Exchange, on the 10th, a sale of 10,000 silver certificates was made at 60. This is the first transaction in these certificates for twelve months.

Copper is quoted at 10c. Pig iron shows little improvement. Pittsburg reports a recent sale at $9 83. The actual cost to the manufacturer is set at $9.68. The Pennsylvania Railroad Co. is reported to have recently made a purchase of 30,000 tons steel rails at $22.

New Yurk Prices.

NEW YORK, Jan. 17.—Following are the closing prices for the week:

	Silver in—

Practical Treatise on Hydraulic Mining.

BY AUG. J. BOWIE, JR.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on heavy grades, methods of mining shallow and deep placers. history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdys, rockers. undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc. A very practical work for gold miners and users of water. Price, $5, postpaid For sale by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

MINING SHAREHOLDERS' DIRECTORY.

Compiled Every Thursday from Advertisements in the Mining and Scientific Press and Other San Francisco Journals.

Belcher S M Co, Nev	C L Perkins, Mills Building	Jan 29

Mining Share Market.

SAN FRANCISCO, Jan. 17, 1895.

There was considerable manipulation during the week, stock being thrown upon the market with disastrous effect to several small operators. An effort to bear Con. Cal. & Va., and Ophir was only partially successful. An increase of gold in the bullion output of the former mine is reported.

The Mayflower Gravel Mining Company paid a dividend of 10c per share on the 15th.

At the annual meeting of the stockholders of the Sierra Nevada Mining Company 95,264 shares were represented and the following officers elected: Charles H. Fish, president; Charles H. Hirshfeld, vice-president; and A. K. P. Harmon, Thomas Cole and Herman Zadig, directors. E. L. Parker was re-elected secretary, and his financial statement showed a credit of $2443.71. An assessment of 25 cents per share was levied, delinquent February 16.

President Ives of the San Francisco Stock Exchange has appointed the following committees: Executive—James Marks, Charles Paxton, A. F. Coffin, M. A. McDonald and C. W. Fox. Finance—E. Epstein, O. R. Jones, James L. King. Stock List—A. J. McDonald, O. W. Marye, E. P. Barrett, R. F. Rodgers and S. Dixon. Commission and Rules—J. H. Crocker, A. G. Garnet and Werner Stauf.

The Debris Commission has granted permits to Goodman Brothers, Goodman & Bund and Hadley & Bolles to work their mines near Volcano, Amador county. Several other applications for permits were not acted upon.

Alta, and the 12th floor above the 1650 level in the Con. Va., share the greatest present attention as to the probability of immediate development.

The following illustrates the changes of the week:

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING JAN. 8, 1895.

532,315.—CAR COUPLING—Downey & Hummer, Bishop, Cal.

532,334.—TROUSERS' STRETCHER—K S. O'Keeffe, S. F.

532,215.—LAMP HEATER—A. L. Robbins, Los Angeles, Cal.

532,116.—GRAVE IMPLEMENT—S. Todd, Alturas, Cal.

532,407.—NON-CONDUCTING COVERING—E. W. Tucker, S. F.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

CARBURETOR.—Edmund R. Cook, Sacramento, Cal., assignor of one-half to Warren F. Drew and Moses M. Drew, Sacramento, Cal. No. 531,780. Dated Jan. 1, 1895. This carburetor is more properly a gas generator, and the invention consists, in connection with an air pump and an oil vessel, of a rotating screen reel composed generally of concentric cylindrical screens separated from each other, the outermost of the series being provided with cups or buckets for elevating the oil, which oil, by means of suitable directing plates between the screens, is guided and directed invariably to the center of the screen, and in its course meets with a flow of air which is admitted to the center of the screen and is forced outwardly against the incoming oil.

CARBURETOR.—Edmund R. Cook, Sacramento, Cal. Assignor of one-half to Warren F. Drew and Moses M. Drew, Sacramento, Cal. No. 531,779. Dated Jan. 1, 1895. This carburetor is especially intended for explosive engines and consists essentially of a mixing chamber communicating with the engine, an air inlet communicating with a mixing chamber, a sleeve in said air inlet forming a vaporizing chamber exposed to the inrushing air and communicating with the mixing chamber, a normally closed spring-controlled valve for feeding oil to the vaporizing chamber, and a means actuated by the inrushing air for operating said valve. The operation of the carburetor is wholly automatic and the mixture of air and gas is regulated to the needs of the engine both in volume and proportions. The inrush of air is effected by the sucking of the engine, and the volume and force of this air are wholly dependent upon the engine; therefore, when a large quantity of air is drawn in, it opens the valve to a greater extent, and thus feeds more oil, and, consequently, the amount of gas formed is commensurate with the volume of air. When less air is drawn in, the valve is not opened so far, and less oil is supplied, less gas is formed, and the mixture is still proportioned, and is proper for the requirements of the engine.

CAR COUPLING.—Wm. Chas. Downey and John Charles Hummer, Bishop, Cal., assignors of one-third to W. M. Richards, Keeler, Cal. No. 532,815. Dated Jan. 8, 1895. This car coupling relates to the old-style link and pin class, and is used in connection with means, controllable from the side or top of the car, for lifting and dropping the coupling pin, and for adjusting, leveling and guiding the link into the opposing drawhead chamber. The link-adjusting mechanism consists of a freely suspended slidable piece or plate having its forward end upturned, and its rear portion weighted, said piece or plate being mounted in suitable bearings, and having a bent or deep groove at its rear, whereby, when it is moved forward, its bent or grooved portion enables its weighted rear end to drop, and, thereby, elevate the front end, which, coming up under the link, levels and adjusts it, so that it enters the opposite drawhead with accuracy. Means are provided, operated from the side of the car, for actuating this adjuster plate, so that the link may be readily controlled. The means for lifting the pin consist of a rock-shaft on the car end, having a crank arm engaging adjustably the head of the pin, and said shaft is operated from the side of the car by means of suitable cranks.

Notice of Assessment.

REED MILL AND MINING COMPANY—Location of principal place of business, San Francisco, California. Location of works, Ferguson Mining District, Helene, Lincoln County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 31st day of December, 1894, an assessment (No. 1) of two (2) cents per share, was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, room 33, tenth floor, Mills Building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 28th day of February, 1895, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on WEDNESDAY, the 3d day of April, 1895, to pay the delinquent assessment, together with the cost of advertising and expenses of sale.

By order of the Board of Directors.

JOHN H. ISHAM, Secretary.

Office, Room 33, tenth floor, Mills Building, San Francisco, California.

Notice of Assessment.

GOULD & CURRY SILVER COMPANY—Location of principal place of business, San Francisco, Cal.; location of works, Virginia, Storey county, Nev.

Notice is hereby given that at a meeting of the Board of Directors, held on the 17th day of January, 1895, an assessment (No. 73) of fifteen cents (15c) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, room 69, Nevada block, 309 Montgomery street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 19th day of February, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on TUESDAY, the 12th day of March, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

ALFRED K. DURBROW, Secretary.

Office—Room 69, Nevada block, 309 Montgomery street, San Francisco, Cal.

RUPTURE!

IT has been considered by the medical profession that hernia—commonly called rupture—was incurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But DR. J. C. ANTHONY, of 86 and 87 CHRONICLE BUILDING, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patient no pain, and those living near enough do not lose any time only while in his office once or twice weekly. He guarantees every case he treats, and does not ask a man for a dollar unless he cures him, so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medical College, of New York City.

HEALD'S

Business College,

24 Post Street, - San Francisco.

FOR SEVENTY-FIVE DOLLARS

This College instructs in Shorthand, Type-Writing, Bookkeeping, Telegraphy, Penmanship, Drawing, all the English branches, and everything pertaining to business, for full six months. We have sixteen teachers and give individual instruction to all our pupils.

A Department of Electrical Engineering

Has been established under a thoroughly qualified instructor. The course is thoroughly practical. Send for Circular. C. S. HALEY, Sec.

—THE—

Ore Deposits of the United States.

By J. F. KEMP, A. B., E. M., Professor of Geology School of Mines, Columbia College.

Second Edition, Revised and Enlarged, New Illustrations.

A practical review of the ore deposits of this country. A valuable addition to up-to-date mining literature, of value to the Pacific coast. Sent postpaid upon receipt of price, $4.00. Address

Mining and Scientific Press,

220 Market Street, San Francisco. Cal.

Adamantine Shoes and Dies

—AND—

CHROME CAST STEEL

Cams, Tappets, Bosses, Roll Shells and Crusher Plates.

These castings are extensively used in all the mining States and Territories of North and South America. Guaranteed to prove better and cheaper than any others. Orders solicited subject to the above conditions. When ordering, send sketch with exact dimensions. Send for Illustrated Circular.

Manufactured by CHROME STEEL WORKS, Brooklyn, N. Y.

H. D. MORRIS, Agent, 220 Fremont St., San Francisco.

Special attention given to the purchase of Mine and Mill Supplies. Stamp Cam.

Platinum.

If platinum continues to advance in price, gold will soon be no longer distinguishable as the precious metal, as the continued rise will cause gold to be as cheap in comparison as silver is to gold. If an astute business man had foreseen this rise, and made a "corner" in platinum, he would have done a good stroke of business, for the price of platinum has increased five times during the past three years and is on the upward grade. The cause of this enormous appreciation is the demand for electrical purposes, and the output of the mines has not kept up with the demand. As electricity is brought home to the public the demand and price will increase, for there are several uses to which platinum is put for which no other metal has yet been found suitable. Notably among these are contact points and leading in wires for electric lamps. Electric bells even now are often fitted with contacts which resemble the real thing and yet are but a sham. In the other case the co-efficient of expansion is the valuable feature. Therefore the problem is to find a metal which will not oxidize on being exposed to the effects of the "break" spark of an inductive circuit and to get one which will make a tight joint with glass and has the same co-efficient of expansion as that material.

The Ideal Steam Oil Refiner

FOR STEAM POWER PLANTS

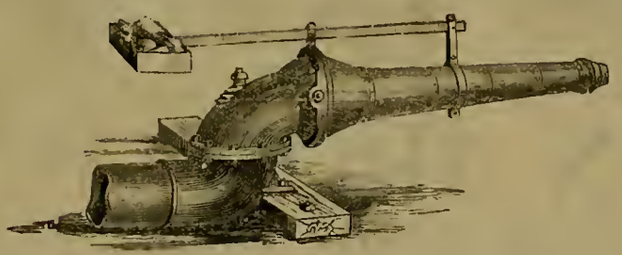
The Purity Oil Filter

FOR WATER POWER PLANTS

Will reclaim your waste oil and make it equal and often better than new oil. Will reduce your oil bills 50 per cent and save your bearings. In use with the largest and best plants everywhere. For prices and particulars, address

D. M. DOUB, 137 First Street, San Francisco, Cal.

IMPROVED FORM OF HYDRAULIC GIANTS.



The above cut illustrates the IMPROVED FORM OF DOUBLE JOINTED HYDRAULIC GIANTS which we manufacture, and which are pronounced far superior to the SINGLE-JOINTED style. The latter, however, we furnish when requested. Prices, Discounts and Catalogues of our specialties of Hydraulic Mining Machinery sent upon application.

JOSHUA HENDY MACHINE WORKS, 42 Fremont St., San Francisco.

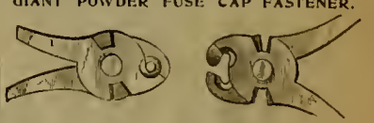
DEWEY & CO., PATENT SOLICITORS.

220 Market St., San Francisco, Cal.

MINING

DIPLOMAS AWARDED. Courses in other trades, all including thorough instruction in Mathematics and Physics. Send for FREE Circular, stating subject you wish to study, to The Correspondence School of Mines, Scranton, Pa.

GIANT POWDER FUSE CAP FASTENER.



The instrument presented in the above cut is a new and grand little invention; being designed to save life and limb, and innumerable lawsuits, by doing away with the dangerous operation of digging out wet and unexploded loads, where Giant Powder is used in mining. The instrument is made of the finest cast steel, and crimps the cap on the end of the fuse *firmly* and *absolutely water tight*. There is also a Fuse Cutter attached. **Price 75c. each.**

MOODEY & SHERWOOD Fresno, Cal.

FOR SALE.

1 Latest Improved Bruckner Furnace.
2 Chlorinating Cylinders of cast iron, lead lined.
1 set Krom Rolls.

The above in use but a short time. For sale cheap. Address L. C. S., Box A., Mining and Scientific Press Office, S. F.

MINING, IRON AND WOODWORKING
MACHINERY AND SUPPLIES

INGERSOLL-SERGEANT PISTON INLET AIR COMPRESSORS AND ROCK DRILLS

ENGINES AND BOILERS

PARKE & LACY COMPANY

21 AND 23 FREMONT STREET, SAN FRANCISCO, CAL.

The McGlew Ore Concentrator Company.

PATENTED SEPTEMBER 19, 1893. CHEAPEST, SIMPLEST, MOST DURABLE AND CLOSEST SAVING CONCENTRATOR IN USE. FRANK BARRERE, Secretary and Manager.

Can be seen in operation at the Company's works, 132 Main Street, San Francisco.

Office, 116 Davis Street.

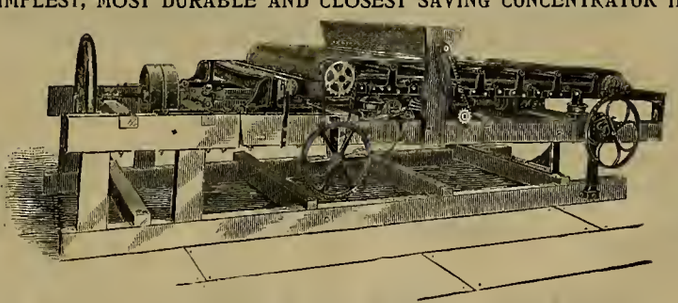
NINETY-FOUR AND ONE-HALF PER CENT
— SAVED —
ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness, combining both Side and End Motion with a Bumping Belt.

SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILST IN OPERATION.

CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE.....$350 EACH
Including prepared canvas belt 4 ft. 6 ins. wide.



FALLS MINE, IGO, SHASTA CO., CAL., May 25th, 1893.
THE MCGLEW CONCENTRATOR COMPANY:—I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years' experience with different concentrators, I believed them to be the best.

Now, after a thorough trial of the McGlew Ore Concentrator, on ores difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ores. It is doing CLEANER and CLOSER work than I had believed possible for any concentrator to accomplish.

Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 94½ per cent; from East ledge, * * * a saving of 92 per cent. The concentrator runs very easy and requires but slight attention. One man attends to rock breaker, crusher and concentrator.

You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily ecommend it to the mining public. Yours respectfully,
E. L. BALLOU, Propr. Ballou Reduction Works.

C. J. Clark, M. E., Gen'l. Supt. Dec. 12, 1891.

MESSRS. ADAMS & CARTER, San Francisco, Cal.—DEAR SIRS: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the Frue in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for TWELVE MONTHS. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to to mention. In order to give an idea of the work they are doing here, I will state that the ore has varied monthly from $5 to $20 per ton and the tailings from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six-foot Frue Vanner too highly, and it is the only table that I would have in my mill.
C. J. CLARK, Gen'l Supt.

Marking Mining Locations.

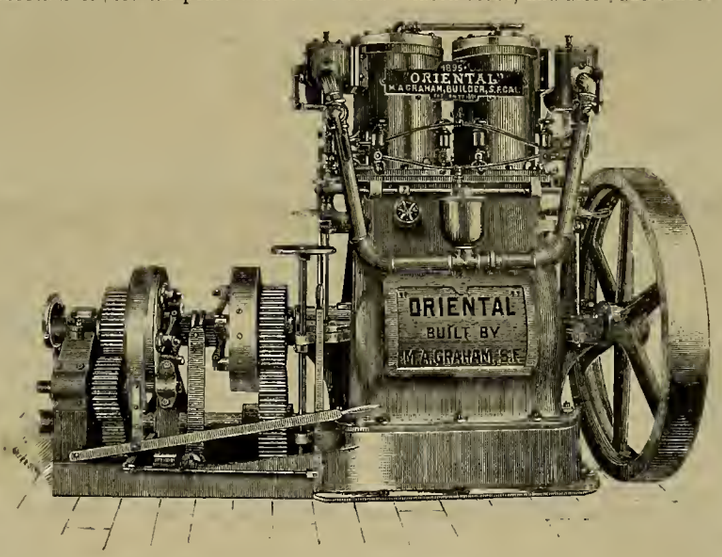
Careless marking of the boundaries of a mining claim at the time of locating may make trouble for the owners, especially should the mine become rich and well known. Then, when it is worth having, plenty of people will be willing to establish claim to it if they can. The locator should, of course, first try to find the vein, and, that being found, should determine its general direction, by which direction he will be governed in marking the boundaries of the claim on the surface. Then, when he records his claim, he should give the course and distance, as nearly as practicable, from the discovery shaft of the claim to some permanent, well-known objects, such, for instance, as stone monuments, blazed trees, the confluence of streams, points of intersection of well-known gulches, ravines or roads, prominent buttes, hills, etc., which may be in the immediate vicinity, and which will serve to perpetuate and fix the position of the claim and render it susceptible of identification from the description given in the record of locations of the district. In addition to this, the claimant should state the names of adjoining claims, or, if there are no adjoining claims, the relative positions of the nearest claims. He should drive a post or erect a monument at each corner of his surface ground, and at the point of discovery or discovery shaft should fix a post, stake or board upon which should be designated the name of the lode, name or names of locators, number of feet claimed, and in which direction from the point of discovery.

It is essential that the location notice filed for record shall, in addition to the foregoing description, state whether the entire claim of 1500 feet is taken on one side of the point of discovery, or whether it is partly on one side and partly on the other side; and in the latter case how many feet are claimed upon each side of the discovery point. It is important that great care be taken in making, describing and marking mining claims in the notice of location for record. An application for a mining claim survey may be declined by the mineral deputy surveyor where the location is not properly marked on the ground and recorded; and when he makes such survey he must give in his field notes the bearings and distances of his corners to those cited in the location notice, and the same must be shown on the official plat of the survey to enable the department to determine the legal propriety of the survey. The provisions of the law must be strictly complied with in each case to entitle the claimant to a survey and a patent. In all cases, if the location was properly made, it was marked upon the ground. If the survey of it was properly executed, it must have been within the limits thus marked, and if the marks of the location and those of the survey are identical the facts must appear stated in the official field notes.

THE Idaho Legislature has adopted a memorial to Congress asking for the immediate passage of the Hartman mineral land bill, now pending before Congress, to the end that the rights of miners and prospectors may be protected within the limits of the Northern Pacific Railroad land grant.

The Oriental Gas Engine.

Among the local industries there is none acquiring more prominence than that of the manufacture of gas and gasoline engines. The cut herewith illustrates a 40 H. P. "Oriental" marine gasoline engine, built by M. A. Graham, 105 Beale street, this city, for a mining syndicate of Lower California for transportation of bullion and supplies. The simplicity of design, and consequent ease with which it can be managed, its reliable action under all conditions, has given the "Oriental" a most enviable reputation among users of gas engines, in consequence of which the works have been for several months principally engaged upon engines for marine purposes. They are now engaged upon a 20 H. P. marine engine for the pearl fisheries of the southern coast, and also a launch engine for New York City. So it would seem the reputation the "Oriental" has obtained at home is reaching more distant shores, and it is only another evidence of the excellency of many of the products of the Pacific coast.



THE ORIENTAL GAS ENGINE.

CONSIDERABLE notice has been given in these columns to the recent co-operative experiment at the Morning mine in the Cœur d'Alene district, which closed down because, virtually, the owners considered themselves unable to pay the men the $3.50 per day required by the Union. The plant was a finely equipped one, the ore a silver-lead concentrating. Figures furnished state the cost per ton of crude ore was as follows: Mining, $1.536; milling, .276; railroad (mine to mill), .108; general expense, .04; sampling, .08; royalty (19%), .475; total, $2.576. This paid the miners $2.625 per day, omitting anything for the use of the plant or tools. The matter illustrates the necessity for the closest management to keep any sort of such proposition going at the present prices of silver and lead.

UTAH ore producers are not renewing their annual contracts with the smelters. The latter appear to have combined on advanced rates, and the producers say they will make no contracts till the fate of silver is more definite than at present. Several of the ore producers talk of building an independent smelter, to be run solely in their interests.

Montana Mine Inspection.

The Montana State Mine Inspector in his sixth annual report gives a general description of the principal mines of the State, with a description of the size and style of engines, cables, etc., and makes many practical suggestions. He favors abolishing the use of crossheads at a depth not lower than 100 feet below the surface, holds that mine owners and managers should permit official inspection in every department of surface and underground work, reminding them that the inspector of mines is sworn not to reveal the secrets of underground workings and deposits, the magnitude of bodies, class of ore and value, or aught else which, if made public, might affect the business interests of owners or leasers, and states that he is accredited with more power than he is granted by law. He cannot stop work in a mine, nor can he even enter a mine without permission of those in charge, any more than a private citizen.

He points out the necessity of greater protection for those who daily enter the mine by cages, suggesting the use of a permanent network of wire not less than three and one-half feet in height on either end, and wire network doors the full width of the cage for either side. These doors could be opened outward and closed again as easily as the bar can be lifted and put down, provided the floor of the cage does not stop below the level of stations.

He urges the formulation of a State code of mining signals, about the same in substance as the Voorhees law passed by our State Legislature in March, '93, saying, "A major portion of the fatal mine accidents which have occurred in Montana during the past fifteen years are attributable solely to the misunderstanding of signals, the forgetfulness of engineers or from ignorance of the code of signals in use when a new engineer takes charge.

"With a universal code of signals it is plain to be seen that hundreds of accidents would be avoided.

"Every engineer and miner would have but one code to learn. This code would be so firmly impressed upon the mind that forgetfulness would be almost impossible. Like the alphabet, these signals would go on from youth to old age, never to be eradicated from the memory when once learned.

"At present there are at least fifty different codes of signals in use, and, when changing from one mine to another, engineers, and even foremen and managers, must learn a new code. This is liable to result in a confusion of ideas, especially where quick work is required."

The report is replete with points for the convenience, safety and welfare of all concerned, and deserves affirmative action.

THE third Government survey of the bay of San Francisco, which will shortly be begun, will, among other things, determine the effect upon the bay of any detritus alleged to have been washed down from the hydraulic mines. It has long been claimed that the depth of the upper part of the bay has not been diminished thereby, as the quantity must necessarily have been very small.

Progress of the Work.

During the week Congressmau Caminetti introduced a resolution that all pending selections in railroad graut interests now awaiting pateuts shall be suspended until Congress takes action providing for the classification of mineral lands in all land grants.

Hartmau, of Moutana, asked unauimous consent for the cousideration of a resolution for the Secretary of the Interior to suspend all action lookiug to the approval of selections aud pateuting to railroads of any lands selected under the rules issued July 9, 1894, until Congress may dispose of the bill now pending in the Seuate and finally settle the question of the classification of granted lauds. Mr. Hartman showed that 1,092,000 acres of land were iuvolved.

Tracey, of New York, objected.

The Committee on the Protection of Mineral Lands, in this city, which has been untiring in its work since its appointment at the State Miuers' Association sixty days ago, has met with an unexpected check in the General Land Office at Washingtou. Uuder the assumption that it was a public institutiou and that the miners of this State have the same rights as other citizens, the committee sent an ageut to Washington, D. C., to examine the records of the General Land Office and find out the exact locatiou of the lands to which the railroad company lays claim, and such other information as can only be there ascertained. H. F. Clark, the agent so sent, reports that he has been refused the right to copy those lists. It is unfair to assume that Mr. Clark is *persona non grata*, so the ouly just conclusion is that some unwarranted influence has succeeded iu closing the doors of this public institution to the Califoruia miners, and the interests of the public are subverted. Protests against the patenting to the S. P. Co. of 65,600 acres in the Visalia district and 14,264 acres iu the Iudependence district have been sent to those districts. These or similar protests would have been ineffectual after next Monday. They are based on the avowal that the lands are more valuable for mineral than agricultural purposes.

The work of the committee is of interest to every one directly or iudirectly counected with the mining industry of the State. The result of the corporation's efforts to secure control of those vast areas of lands would greatly diminish the available amouut of mineral land, and the committee's efforts are in parallel lines with the best public policy and the general good. Upou the active co-operation and substantial help of those most interested in saving the public lands from such absorption depends, greatly, the measure of success that shall attend the committee's efforts.

The U. S. Geologic Survey.

The proper scope of work of the U. S. Geologic Survey has always been a subject of discussion. Just now an effort is being made to check the work of the Survey in certain practical lines, and limit its usefulness, by assailing the motives of those in charge. Motives can always be misconstrued or misjudged, and discussion thereon savors too much of the personal to be admissible in a technical journal. Among other things asserted by the opponents of the Survey's system is that "the work of the Survey should be purely scientific." It is ueither the province nor the purpose of this jourual to fly to the defeuse of the Survey or its Director, but as a well-wisher to all parties in the controversy it is to be said that the quoted statemeut shows a lamentable lack of understanding of public requirements. There is too much of this hidebound, dry-as-dust demand for "pure science," which is largely abstract, theoretical, dilettaute research and observation. The Director of the Survey is attacked mainly because he wauts to do somethiug practical for the miners in the west half of the uatiou, and the opposition thereto is mostly sectional. Director Wolcott recognizes the practical needs of the mining interests of the country, and in this regard, at least, deserves to be upheld.

Every one conversant with the efforts made to have the importance of our mining interests recognized knows how strenuously this paper labored to secure the establishment of a bureau of mines and mining, similar in scope to the recently created Department of Agriculture. The Congressional Committee on Mines and Mining, to which a bill was referred, rejected the proposition, saying that the United States Geological Survey is to all intents and purposes practically a bureau of mines and miuing. Now that recognition is proposed of this fact a cry is raised that Director Wolcott has been "captured by the Western boomers." Uufortunately, sundry journalistic parrots repeat this cry, when duty to the interests they represent and better understauding of the question would impel them to aid instead of retarding au effort to give the mineral interests of California, Nevada, Colorado, Montana, Idaho, Oregon and the Territories attcution commensurate with their importance on the part of the United States Geological Survey.

The assertiou that "the work of the survey should be purely scientific" is illustrative of a belief in some quarters that general geology is the sole scope aud constitutes the just limits of the work of the Survey. Any thing published or worked up by the Survey telliug the miner anythiug of practical value to him is considered outside of aud foreign to the intent of this branch of Government service. But that is the very thing that the Survey is for. General geology, "pure science," is all very well for a pure scientist, but it won't tell a miner anything about how to make his rock pay. It won't tell him of the new processes and methods of miuing. The miner doesn't want a finely published treatise on "The tangible effects of a chimera revolviug in a vacuum." He doesn't care much about a catalogue of rare minerals in a glass case. He is uot specially interested in a monograph on the Megatheriums of the Miocene period, but he does waut some applied science; he would like to get from this Government institution, supported by public taxation, a few practical points on mining and metallurgy; he would like to be given in plain shape the up-to-date condition of miniug processes of value to people now on earth.

Great objection is made to the work of the Survey in giving attention to practical miuiug and metallurgy. But the economic value of these things justifies such attention. The Agricultural Department makes experimeuts, produces seeds, sends them, conducts correspondence, and makes itself useful in the concrete rather than in the abstract, and thus fulfills the purpose for which it was created. The United States Geological Survey need try no such experiments, nor seud samples, but it is within its province to report and record results aud increase the geueral fund of practical information. If a man is working a particular ore in a peculiar way, it is for the Survey officials to so report. As between scientific miners aud practical miners, the latter have the best of it in results and are entitled to recognition in the work done by Government institutions. The utility of the Survey will be better recognized by the miniug community if the ideas of the Director iu this regard arc not hampered by those who stultify themselves in unworthy opposition to intelligent effort for the general good.

Economy—Wise and Unwise.

Retreuchment and reform are the present watchwords and the avowed policy of the Governor and Legislature. Both are necessary, and now is a good time to put them in practice. The State is in bad financial condition aud the taxes are onerous. The appropriation in '91 for the support of the State Government for the two fiscal years beginning with the 1st of July of that year, amounted to $9,748,696; the corresponding appropriations iu '93 were $11,-972,623. These figures are furnished us by the State Controller. What the appropriations for '95 will be is for the present Legislature to determiue. The sum of $6,000,000 a year is too much to annually tax a commonwealth of 1,250,000 people. Aud that $6,000,000 is only half the load. There is another $6,000,000 annually required for county governments. Our present State officers are pledged to economy. They have a splendid field for actiou. We are paying too much for what we get, and are payiug for a good deal that we do not get at all. California pays, every year, for the support of insaue asylums, $800,-000; for State prisons and reformatories, $550,000; for deaf, dumb and blind, $100,000; for feeble minded children, $110,000. Here is an annual tax of $1,560,-000 to support a non-producing and unfortunate class. The State priuting office costs $125,000 a year, the State militia are given $175,000 annually; that annual horse trot known as "the State Fair" has its thousands; every year $27,500 is given the State library; the institution known as "the State Board of Horticulture" gets $15,000 every twelve months; the gentlemeu who have charge of hatching fish have au anuual fund of $18,500; the other gentlemen who look after "Yosemite and the Big Trees" have $14,000. There is also paid out every year for Railroad Commissiouers, $17,870; for State Board of Equalization, $15,250; for Registrar of Voters, $6,-000; for Goveruor's office, $18,900; for Secretary of State's office, $24,000; for State Controller's office, $15,480; for State Treasurer's office, $12,400; for Attorney-General's office, $24,080; for Superintendent of Public Iustruction's office, $8,600; for Surveyor-General's office, $12,280; for employes of Capitol Commissiouers, $18,600; for State Harbor Commissioners, $27,600; for State Board of Health, $5,000; for San Francisco Board of Health, $5,000; for Bank Commissioners aud their employes, $18,800; for Insurance Commissioner's office, $4,800; for State Normal School, $97,000; for Guardian of Marshall's Monument, $600; for office of State Examining Board, $6,400; for Adjutant-Gencral's office, $6,600; for Park Commissioners' office, $6,300; for Commissioner of Public Works, $5,800.

Then there is the Viticultural Board, $15,000 a year; the Labor Bureau, $7,500 a year; the Loan Association Commission, $24,000 a year, and so ou. The records of the State Board of Examiners also show that commissions and boards that perform duties without pay have considerable iucidental expenses.

The above is not oue-half, but it gives a good idea of where the millions go.

Any intelligeut person can see at a glance how inflated all this is. Probably forty per ceut of the abovc is extravagance and waste. It would be wise ecouomy to cut deep and lop off some of those finaucial excresceuces.

But there is true and false ecouomy, wise and uuwise effort at retrenchment. Economy is only the judicious expenditure of money. Results must also be considered. There is one appropriation for a State institution that does more for the good of the State than any other. It is the annual appropriation for the State Mining Bureau. Singularly enough, that is the very one first singled out for legislative action that virtually abolishes it. Mr. Langford, of San Joaquin, has already introduced a bill which, if successful, will deal a blow to the mining industries of the State that will seriously hurt the commonwealth.

It is neither our province nor our purpose to im-

pugn the motives of any legislator, whether from the valleys or the mountains. It is to be presumed that a member of the California State Legislature goes to the Capitol to work for the best interests of the State. Hence, the most charitable view of Mr. Langford's action is to assume that he is incorrectly informed as to the value of the Bureau whose usefulness he seeks to impair, and that he is not acting in defiance, but in ignorance of the valuable interests to which he is antagonistic. This attempt to destroy the usefulness of the State Mining Bureau is an instance of unwise economy. The very last thing that should be assailed by reason of its splendid record of practical usefulness is the first. It looks more like reprisal than economy: more like hostility to the miner than honesty in redemption of ante-election pledges. It is unfair, unwise and uncalled for, and the PRESS gives editorial prominence to this matter, with the intent of calling upon every one in the State directly or indirectly interested in California's great mining industry to voice their protest against such proposed action.

The State Mining Bureau is now at the front as a factor in promoting the State's mining interests; it has given grand aid in directing attention to our mineral wealth; it is the only institution the miners have; the few thousands it annually costs represent not a one-hundredth part of the actual resultant benefit; it is now in the zenith of its usefulness, and he may justly be looked upon as an enemy of the State who would seek to cripple it.

These are strong words; but the facts justify them. With every other industry paralyzed; with a scarcity of money, a dearth of employment and a lowering of wages, the one institution representative of an industry that yearly puts out $20,000,000 in tangible wealth is considered worthy of being relegated to a comatose condition. That is not economy; it is destructive and injurious; it borders on the idiotic. Any one can destroy: it takes work, effort, ability, intelligence, to build up and create, but an idiot with a torch can burn down the grandest earthly creation. It has taken a great deal of hard work to make the Mining Bureau the present potent factor in the State's mineral wealth; every dollar it receives is faithfully and intelligently spent and rigidly accounted for; its results redound to the State's benefits a thousand-fold, and there are many reasons why it should be encouraged and maintained instead of being threatened with dissolution, to elaborate on any one of them being unnecessary to those who can understand it and useless to those who cannot.

If the Legislature is sincere in its intents of economy, it poorly shows it. Already it has beyond all preceding years displayed shameless extravagance. It has this week created a swarm of unnecessary employes in the State capital for the session who daily draw $1524. Over $1500 a day worse than wasted! Yet a few dollars is grudged an institution like the State Mining Bureau that is the means of yearly insuring the development of millions in the great domain of California's mineral wealth.

We call upon the miners and mining men of the State to aid in preventing this infamy—for infamy it is—being done. Nothing but lethargy and inaction will permit such injustice to the State as the proposed legislative action regarding the State Mining Bureau. Mining is the basis of all civilization, all material wealth, all progress. Bullion is the blood of business, the life of commerce, the essence of advancement. The rise or fall of legitimate mining marks the rise or fall of California. True economy, wise legislation, would increase the scope instead of attempting to destroy the only State public institution that benefits the miner and the State, for with the fortunes of the miner is indissolubly bound up the fortunes of the State. We call upon the press and public sentiment to resist this attack upon the prosperity of the State. As a cold business proposition, such interference as that in the Langford act is suicidal.

Obituary.

H. F. REINHART, a prominent mining engineer, residing at Chihuahua, Mexico, was killed a short time ago by the accidental discharge of a gun. He was a native of Mannheim, Germany, and in his 39th year. During his business career in Mexico he caused many million dollars worth of American mining machinery to be imported into that country. He was a resident of this city from '75 to '80.

Manufacturers' National Convention.

A convention of manufacturers has been in session this week at Cincinnati, O. The proposition is to form a National Association of Manufacturers, which shall embrace among its purposes:

1. The cementing of a national organization of the manufacturers of the United States, for the purpose of considering national questions affecting their interests.

2. The advocacy of carefully considered legislation to encourage manufacturing industries of all classes throughout the country.

3. The discussion of ways and means whereby trade relations between the United States and foreign countries may be developed and extended.

4. The establishment in South American capitals and other desirable points of expositions for the display of American products.

5. The extension of the commercial marine of the United States.

6. The recognition of the Nicaragua Canal and the control of the same by the United States Government.

7. The re-establishment of reciprocal trade relations with foreign countries.

8. Such other topics as may be agreed upon by the convention.

This convention is non-political, non-partisan and non-sectional.

The preliminary work was satisfactory, and much resultant good may justly be expected.

The arrangements for the convention were as elaborate as for a national political convention. The original fund of $10,000 was doubled. Over 1200 delegates wrote that they would be present. While it is proposed to open up commerce with the South American republics, yet all the interests of manufacturers were considered.

Concentrates.

THE Gordon mine, at Baker City, Or., has been sold to Boston men for $4000.

SENATOR WOLCOTT'S BILL to establish a coinage mint at Denver has been reported favorably.

THE Eagle Bird mine near Washington, Cal., has closed down, the deep snow having broken the flume.

THE *Times* says that there is scarcely a day that prospecting outfits do not pass through Yuma from California.

THE dry house at the Omaha mine, Grass Valley, was destroyed by fire last Monday night. The miners lost their clothing.

THE report of the Alaska-Treadwell mine on Douglas Island, Alaska, for December shows an average of $2.24 per ton for the ore milled.

THE Kansas City Consolidated Smelting Company has closed its Salt Lake office and moved its western headquarters to Butte, Mont.

THE November report of the Alaska-Mexican mine on Douglas Island, Alaska, shows that the ore averaged $2.29; the cost of working was $1.95 per ton.

THE Black Butte mine, near Canyon City, Or., has been sold to Hall & Smith of Portland; they announce their intention to erect an extensive reduction plant.

THE new spur wheel for the Providence hoisting works has arrived at the mine at Nevada City. The miners have gone to work again, after being idle three weeks.

THE Siskiyou Gold Mining Co. has incorporated in Tacoma, Wash.; incorporators, W. H. Reid, J. L. McMurray and S. C. Slaughter; capital stock $100,000, divided into 10,000 shares of $10 each.

NEARLY every mine in Grass Valley was shut down a part of this week by reason of a break in the South Yuba ditch. Deep snow has occasioned much damage to flume and ditch property.

RESUMPTION of work in the White Horse mines seems to be the order of the day, says the Virginia *Enterprise*. It is probable that the Washoe, Defiance, Jim Blaine and Black Warrior will begin prospect work in the near future.

THE Austin *Reveille* says the Imperial Mining Company of Kennedy, Nev., has not paid its men, and that the liens filed on the property are not valid. There is abundance of ore in Kennedy, but it cannot be successfully worked in the Imperial mill.

THE Gold Eagle, Golden Mound and Ocean Wave gold claims in Ellsworth district, Yuma Co., Arizona, have been sold to Lewalling and Kimball for $9000. There is good water within half a mile of the camp. The ore is free milling and runs as high as $80.

THE Orleans Mining Co., at Nevada City, is adopting the co-operative plan. The owners have increased the capital stock to 60,000 shares, and are selling 12,500 shares at one dollar each. The miners employed take $2 per day in cash and $1 per day in stock.

THE Elkton Mining & Milling Company has given a title bond on its property at Cripple Creek, Col., the Kentucky, Bell and Elkton mines, to J. M. Parker, D. Fletcher, A. Buckler and others for $500,000. This is one of the most important sales in the history of Cripple Creek.

THE Union Leasing and Mining Company of Leadville, Col., has taken a lease for a term of five years on the plant of the American Smelting Company in that city. This plant has been idle since the collapse of silver in 1893, but will be put in prime operating condition with the addition of a number of roasting furnaces.

THE Montezuma Mining and Reduction Co. are shipping copper from Fairbank, Arizona, from their property at Nacosari, 140 miles from Fairbank. The ore averages 15 per cent, concentrated to a 50 per cent proposition, and smelted under a process that turns out a ton of matte from a consumption of two tons of coke.

GREAT interest prevails at Silver Cliff, Col., over a new gold strike four miles from there. The rock formation and ore are said by Cripple Creek experts to be identical with those of Bull Hill and Has Been, made by the best assayers in the State to show from $12 to $700 per ton gold and silver values. The vein is on the Bassick mine belt.

J. A. ELLIOTT, of Butte, Montana, has invented a gold machine for which great claims are made. The inventor says that ground running fifteen cents to the yard can be made to pay by working it on a large scale and with favorable surrouudings. Big money can be made with ground running from twenty-five cents to $1 per yard.

ANOTHER big gold strike is reported in the New York and Chance mine at Creede, Col. Heretofore the mine has been a rich silver producer, and has earned several hundred thousand dollars for the owners. The strike was made on the 1000-foot level. A shipment made carried fourteen ounces of gold and 400 ounces of silver. Henry Wolcott and Judge O. E. Le Fevre, of Denver, are the principal owners.

AN EASTERN SYNDICATE has secured control of the old copper mine located near the headwaters of Clover creek, Union county, Or. It is said that a large number of workmen will be employed this winter in development work. The mine is one that was discovered several years ago, and, although rich in copper, it has never been extensively operated. It is about six miles from North Powder, where supplies are purchased.

A YOUNG MAN named Jas. Ryan was killed at the Coffee Mill mine, near Mokelumne Hill, last Sunday. He and his partner were working in a single drift. The timbers indicated heavy pressure and Ryan sent his partner for a lagging to strengthen the timbers. His partner had gone but a short distance when he heard a crash. Rushing back he found Ryan under a mass of earth. His head was not covered, but a lagging lay across his throat. It took two hours to remove the earth and extricate the body.

INQUIRY is progressing regarding the recent awful explosion at Butte, Montana. A former employe of the Kenyon-Cornell Company says there was usually kept on hand anywhere from five to forty boxes of giaut powder, each holding fifty pounds. The room in which the powder was kept was surrounded by several thousand wrought-iron "rabble heads," pieces of iron ½x4x6 inches, used for heads of skimming tools in smelters. They had been piled around the powder to protect it from a bullet, should any be fired against the building, and were considered to afford full protection.

THE De La Grange Hydraulic Mining Co., incorporated at $5,000,000 under the laws of Colorado, has twelve miles of ditch for its placer property in Trinity Co. The Junction City Mining Co. is capitalized at $400,000 to work in the same county. The Minersville Mining Co. is a close corporation owned by Messrs. Beaudry, Duvergey, Chartier, Cumenge, and Count Kergoldy. The latter company has in operation six miles of ditch, carrying 4000 inches of water, with a 300-foot pressure, and is running two giant nozzles, each ten inches in diameter.

A SHAFT is being sunk in the heart of the town of Oroville, Cal. The plan is to sink to bedrock a depth of fifty feet and thence drift out the gravel. Past prospecting has shown that one of the richest beds of gravel in the State is in the bar of Feather river upon which the town of Oroville is built. The great difficulty in the past has been to cope with the water. The present projectors believe they have machinery that will drain the ground. Drifting out the gravel at that depth will not disturb the surface, and mining may be successfully prosecuted under the entire town if the water can be handled.

A CASE involving 160 acres of land in Calaveras county has been on trial this week in the Land Office, being a contest as to whether it was mineral or agricultural land. The decision was in favor of the miner. The case is of considerable local importance to the inhabitants of the West Point mining district. The land adjoins the town of West Point, and has been used since the 50's for mining purposes by various parties. Extensive mining operations have in the past been carried on thereon. On one claim, the Zacerateo, some $125,000 has been expended. The land is seamed in many places by quartz veins.

J. E. FRICK, one of the stockholders of the White Swan Mining Company, an Oregon corporation, has begun suit in the superior court in Chicago on behalf of himself and other stockholders against F. W. Ferry and A. S. Wright of Ferry & Wright. The plaintiff alleges that the defendants entered into an agreement to purchase the White Swan gold mine at Baker City, Or., for $90,000, and were given possession and started to work it, but in a short time abandoned the property, and refused to pay for it. The plaintiff now seeks to collect the amount which the alleged purchasers agreed to pay, with damages. The defendants are dealers in mining property, who have had their headquarters in Chicago.

Personal.

LOUIS ROBINSON, who had charge of the Machinery Department at the World's Fair, has gone to Montevideo as fleet engineer of the South Atlantic squadron.

U. S. GEOLOGICAL ENGINEER M. BISHOP is at Bisbee, Arizona, to review the new boundary line between Mexico and the United States. Lieut. Bishop's party has been in the field for the past eight months, and has lately been transferred to the S. E. Div. of the Geological and Topographical Survey for the War Department.

LIEUTENANT MEIGS, of the Bethlehem Iron Company, who negotiated the contract which the Russian Government recently awarded to the company, has returned from St. Petersburg, bearing all the papers for the order. The contract is for 1500 tons of unharveyized armor plate, 1200 tons of which is sixteen-inch plate and 300 tons seven-inch plate. The value of the contract is $1,250,000. The contract will keep the plant busy a year.

Mining in California.

A Review of the Situation Shows the Industry to Be in a Most Prosperous Condition.

At no time within the past fifteen years has the mining outlook in California been so promising as now. During the past two years there has been a marked improvement in the situation. Numerous new enterprises have been organized and placed on a substantial basis, and are now paying. Fully as many mines, long abandoned, have been, or are now being, reopened under more favorable auspices than obtained at the time when operations were discontinued.

In this State there are twenty-three counties where mining is an important industry, and among these there are several in which it constitutes the chief or only one. Besides these there are eighteen other counties in which mining or quarrying give employment to a large number of men.

The continued successes of some companies, numerous rich strikes in old mines and the discovery of gold rock in places where it was heretofore unknown, and the repeated successes of newly organized companies have all had a direct and beneficial effect in directing the attention of capital to this State of of phenomenal resources. Not only have resident capitalists made large investments, but moneyed men have come from many Eastern cities and from Europe seeking secure and profitable investment. Thus far, most fortunately, we have only successes to chronicle. "Wild cats" have not yet put in an appearance, though these, the most detrimental of all things to legitimate mining, are likely to appear at any time. The men investing are showing a disposition to engage in mining on a strictly legitimate basis, which, indeed, is the only basis on which mining enterprises can hope to exist in these days.

There is no denying the fact that the unprecedented depreciation of silver has in a large measure added to our prosperity. Large capital interested in silver properties was actually "forced out of business." Naturally this capital would seek a new channel for investment. A look over the country quickly showed that the broadest, most legitimate field lay in California. Her mines had already produced $1,200,000,000 in gold, and there was every indication that hundreds of millions more were obtainable if a combination of capital, labor and experience were directed this way.

This increase of prosperity has not come upon us suddenly. For two years or more past there has been an increasingly greater interest taken in our mines, until within the past six months it has assumed the proportions of a "rush for gold." It is to be most sincerely hoped that the legitimate will be strictly adhered to, as one disastrous, ill-advised investment will do more to retard new enterprise than a dozen successes can overcome.

Some of our most famous mines, notably about Nevada county and in Amador, have been worked continuously and successfully for years. Still, there always remained that doubt, "Do these mines go down?" The experience of the past and that of today has demonstrated in a practical and convincing manner that these great leads "do go down," and, moreover, that the greatest depth yet attained on any vein, which is almost half a mile, shows no falling off in the value of the quartz at this great depth. There are shafts in Mariposa county 1500 feet deep, in Calaveras equally deep, and in Amador there are several shafts down more than 2000 feet, and one 2400 (the old Eureka) at Sutter Creek. There are a score or more of shafts over 1000 feet in depth in California, and some of the deepest are being sunk still deeper with the most encouraging results.

Prominent among the long-abandoned mines now being reopened, and it may be said in each case with most encouraging results, are the Rosalia in Riverside county, where a vein worked years ago by Mexicans to water line has been reopened and the workings are in a fine vein of quartz that will pay.

In Mariposa county the great mines of the Cook estate near Coulterville have passed into other hands and will be thoroughly rehabilitated. These mines have lain idle for years. It has also been stated that the mines of the Mariposa estate are to be reopened and equipped once more.

In Tuolumne county a dozen old mines long abandoned are once more the scene of activity, and nothing but prosperity is anticipated from them. Prominent among these is the Mammoth at Jacksonville, which recently passed into the hands of the Sierra Buttes Company. This company has also purchased the Whitlock mine, five miles north of the town of Mariposa, and are outfitting it with a fine plant of machinery. This is one of the most promising properties in that county.

In Calaveras county the Gwyn mine near Mokelumne Hill, abandoned in 1882 at a depth of 1500 feet, is being reopened. The Boston mine is also being worked once more. The Calaveras Consolidated on Carson Hill has put in two busy years opening that property. Besides these, there are several smaller properties where activity has succeeded lethargy or abandonment. Among these are several drift mines and hydraulic enterprises.

Amador county is a prominent field of operation among old mines. The leading mines are the New London and Pioneer at Plymouth, and it is said the Alpine mine in the town of Plymouth is also to be reopened. At Sutter Creek the Mahoney mine is again in operation, and south of Jackson the Hardenburgh is again in bonanza.

Farther northward, in Butte county, the famous Magalia drift mine has been purchased by J. B. Haggin, and promises, if reports be true, to prove a large producer. Many other instances might be cited, as this revival is extending all over the State and is reaching beyond our borders.

There are, too, numerous new enterprises where capital has been interested in the development and equipment of promising prospects. In San Diego county the Gold Rock mines were purchased by an Eastern corporation, known as the Golden Cross Mining Company. The mines are six miles from Ogilby station, on the Colorado desert, and fourteen miles from the Colorado river, from which water is pumped to the mine, being forced to an altitude of nearly 500 feet. A forty-stamp mill crushes 100 tons of rock daily. The ore shoots are very large. This concern demonstrates the possibilities on the desert.

In the Julian district, also in this county, all is activity after fifteen years of stagnation. Twenty or more mines are in operation, mostly by leasers, who have the rock crushed in custom mills. Pine Valley and Mesa Grande districts are also active.

In Riverside county the Good Hope has passed into the hands of Eastern people and has been completely equipped. The Lost Horse and Pinyon Mountain mines, on the Colorado desert, have produced several thousand dollars in the past year.

In the San Bernardino mountains several new companies are at work, and it is said Baldwin's Gold Mountain mine is to be equipped once more. This mine was abandoned years ago, and the camp—Blairstown—was completely deserted. Tools were left lying promiscuously about, doors of houses stood ajar, and the place presented every appearance of sudden desertion. Since then the eighty-stamp mill burned, and all but two or three of the houses have been moved away; but the sound of the whistle and the thunder of stamps are again to reverberate among the pine-clad hills of that vicinity, so it appears. In the eastern portion of San Bernardino county the mines of Vanderbilt district have proven valuable and at least two of the companies there are operating successfully. Two new districts—Shadow Mountain and Gold Stone—have been discovered in that section, and near Cajon mountains gold has been found at the east and west end of the range.

There is a renewal of activity in the counties east of the Sierra Nevadas—in Alpine, Mono and Inyo counties. Many of the old mines are once more being worked by new owners or leasers.

The long-continued and almost unparalleled output of the Utica-Stickles group of mines at Angels Camp, in Calaveras county, has given an impetus to everything in that section, and many new enterprises of more or less promise have been promulgated.

In addition to the mines already mentioned in Amador county, there are several others deserving of more than mere passing notice. The Argonaut Company, whose property adjoins the rich Kennedy on the south, are sinking a three-compartment shaft, which it is intended to carry to a depth of 2000 feet before suspending operations in that direction. This shaft has been started in the hanging wall, and it is estimated that it will reach a depth of 1000 feet before encountering the veins, thus showing clearly the great faith of the company in their mine. These extensive operations are based on the result of work in the Kennedy, which is 2250 feet deep below the croppings.

A mile southeast from the Argonaut another deep shaft is being sunk by the Alma Company. On this same great fissure, between Jackson and Sutter Creek, a shaft has been sunk over 1000 feet on the South Eureka mine, and considerable other development done, representing an outlay of many thousands of dollars; and yet it is only recently that pay rock has been discovered, and the indications now are that the South Eureka will become as famous as some of its neighbors. Near Plymouth the Bay State is in bonanza and a mill is in operation. The Philadelphia mine, recently purchased by an English syndicate, is being developed, and at Nashville the same company has built a twenty-stamp mill on their mine there.

In El Dorado county there are several new enterprises, prominent among which is the Oro Fino or Big Canyon mine. It was here that a mill having 1400-pound stamps was erected. It does not appear likely, however, that this innovation is likely to become a permanent feature.

In Placer, Nevada, Butte, Plumas and Shasta counties there have been numerous new enterprises, notably at Iron Mountain.

In Siskiyou county there are over 400 operating mines, a large number of which are new. Trinity is now one of the foremost mining counties. The mines are mostly of the hydraulic class, which in this county and in Siskiyou have never been enjoined.

The revival of hydraulic mining in those counties where it has been prohibited by law will tend to very materially increase the gold production. There have now been about eighty applications made for permits to resume operations under the restrictions of the law regulating hydraulic mining. Of these more than half have been granted.

Although there has been such a revival of interest in gold mining in the State within the past year, the general result has not been effected in a marked manner. But the year 1895 will undoubtedly show a very considerable increase in the total gold production. A great deal of time has been spent in rehabilitating old mines, constructing machinery, etc., and getting ready to work, and the increased production may be expected to follow in the near future.

The silver mining industry is still centered chiefly in the Calico region, in San Bernardino county. The litigation so long pending has been compromised and the several properties placed under a single management, and it is currently reported that these mines are to be again operated on a large scale once more.

The New Almaden mine, the great quicksilver producer in Santa Clara county, after a period of depression, is once more in bonanza, and report indicates that this mine will again make a large output. The great quicksilver producers are now in Lake and Napa counties. In the former county the Great Western and Mirabel, and in Napa the Atna, are the great mines. Trinity county is also furnishing a considerable quantity of quicksilver. In this county the Altoona and Integral mines have come into prominence. Quicksilver occurs in many places in the State in unusual forms, in association with gold, etc., but these occurrences are of geological interest only.

Copper mining has declined materially within the past two years, the principal producers, at Copperopolis, having been shut down.

The output of other mineral products has fallen off in some instances, as in clay, chrome and manganese, and in the manufacture of paving blocks, but the increase in the output of building stones, such as granite, sandstone and marble, will more than offset any shortage of the other articles mentioned.

The mining or borax has continued uninterruptedly and indications are that the output will be materially increased by reason of the discovery of large deposits of rock near Calico which contain considerable quantities of calcium borate.

The mining industry as a whole, however, is most promising, and every feature of it points to a long continued era of prosperity.

Within the past two years electricity has been successfully introduced in mining in California, and there is no doubt it will in the future become a very important factor in mining economics, particularly in the transmission of power to points difficult of access or where fuel is expensive. Thus, in Mono county, an electrical transmission plant has been established at the Standard mine, which has for a motive force a mountain stream more than twelve miles distant from the mine. It is in practical and successful operation and effects a large saving in operating expenses.

The perfection and cheapening of metallurgical processes is also doing much toward assuring success. The cyanide process is evidently also destined to work wonderful results when more thoroughly understood.

W. H. STORMS.

San Francisco, January 21, 1895.

A New Mine Cage.

A. Gray, of Sheridan, Montana, has a new mining cage, now in use at the Hope and Leiter mines. The chairs are made a part of the cage and can be thrown in or out at will. The station tender can never leave the chairs in, as they fly back as soon as the engine takes the load off of them. They can be used in making repairs to the shaft, such as retimbering, etc., as they will rest on any set of timbers, and the men employed in the shaft can feel much safer with the cage resting on the chairs than if it were hanging by the rope or cable. Allowing the cage to drop on the chairs at a station is a source of trouble at all the mines of that district, as the chairs are now arranged. With this cage, it is claimed, the only way damage can be done is by dropping the cage into the sump or by hoisting it into the sheaves. With the old-style cage, the old bottom can be taken off and another bottom with the chairs substituted in about three hours. At the Leiter mine the cage was in running two and one-half hours from the time work began on the change, and it is claimed that it costs less to substitute the new bottom and chairs than it does to put in an ordinary set of chairs.

Effect of Failure of Coal Supply.

A hundred years ago the world got on nicely without the steam engine. In the last year of the last century there were but three steam engines in the United States, yet to-day a failure of the coal supply to existing engines would not only paralyze industry, but through the interruption of transportation of food products, and the stoppage of water works and sewage engines, would introduce widespread physical suffering.

Mining Reports and Mine Salting.*

NUMBER III.

By WALTER McDERMOTT.

I wish now to introduce another personal experience for the sake of the morals contained in it, and as bringing out some of the special risks to be guarded against in mine examination. The story is at my own expense, and may, therefore, be somewhat unusual in the transactions of a scientific institution. I am not afraid of the example being followed to the injury of the reputation for shrewdness of mining engineers generally. It is not pleasant to write oneself down as an ass in any form: and personal experience which, if related, might lead to such conclusions are usually kept as private as circumstances will permit. Some experiences which might be very instructive if published, but which naturally do not get known, are those arising from salting when the expert never knows himself of its occurrence.

A few years ago, an English mining engineer and friend of mine brought to me in New York—where I then had a testing mill and assay office—a series of average samples he had taken from a silver mine in the Rocky mountains, and also half a ton of the average ore for a milling test. The samples came out very well, the milling test showed no difficulty in treatment, and the engineer's report to his English principals was quite a glowing one. For financial reasons the purchase fell through in London, and a year later the owner of the mine called to see me about the property. I had been so well impressed with my friend's report on the mine, and the owner's description, that I made offers to purchase on behalf of an English company, subject to examination. Before going so far, however, I got a report from a mining engineer resident in the west, and whose name is well known, confirming the owner's statement as to quantity and average grade of ore in sight. In addition to this, I had copies of statements by two other western engineers, showing the mine to be valuable if the ore were worked by milling process instead of by shipment to smelters, as had been done in the past. On this I visited the mine and sampled it carefully, taking some 1200 lbs. of samples, and sealing the sacks in the mine by wire through and round the necks, and held by a special lead seal of my own. I wanted large samples to confirm previous milling tests, as the matter of treatment seemed an important one; but as I could not carry about me, and sleep with 1200 lbs. of ore, and no vigilance would prevent the possibility of value being worked into the sacks if once lost sight of, I took a special precaution against salting in the following manner. The ore occurred as a bedded deposit, and, outside of occasional pockets of good ore, was reported to be of an average assay value from thirty to fifty ounces of silver per ton by the different engineers who had examined it. It was a question of milling the full width of the bed, which averaged about six feet; and the appearance of the ore lent itself wonderfully well to the theory of its average value. I, therefore, took in addition to twenty-six average samples seven special full sack samples from different parts of the mine, each of which consisted only of large lumps of the poorer ore, without any fine admixture. The object was to have samples which could be readily cleaned when once in my own office, and, therefore, which would be unaffected by any salt introduced in a fine or liquid state into the sacks after sealing. With certainty that there had been no salting, if these lump samples showed a fair silver contents, there could be no doubt whatever as to the value of the deposit.

In this material world good intentions are by themselves very inadequate. My little programme, framed for my own protection, was in an evil moment slightly changed, and thereby ruined. Owing to pressure of enquiry for a preliminary report I decided to crush five of my seven test samples in a neighboring sampling works, and so satisfy myself as to the lower grade of ore which would determine the probable value of the mine for me. I took every precaution by cleaning up the crusher and rolls myself, and dusting off the lump samples, and crushing and quartering down to the assay samples, which I took in duplicate. One of the sets of samples I gave a local assayer who was I knew interested, and would not have been of course reliable if unchecked. The second set of samples I kept myself in a valise in my bedroom. Subsequent events showed that these private cheque samples were got at, and that the whole mining camp was honeycombed with a six years' standing conspiracy. I had still in reserve the two other lump samples sealed as taken, and which with the other twenty-six average samples were sent on to New York to await my return. As bad luck would have it, however, I was stopped by telegram on my return, and had to go farther west to examine another mine; and the samples arriving before I did, were crushed and assayed by my assistant in New York without the special precaution necessary for the two lump samples of cleaning before crushing.

During the night preceding the shipment of samples the gang interested worked into each sack a dose of extremely fine divided precipitated silver, which can be purchased in the west from leaching works using copper plate precipitation. In the final crushing and mixing for assay samples the "salt" became properly incorporated, and appeared only in the results. Investigation later showed that the lump samples alone contained naturally about two to three ounces of silver per ton, but when properly doctored they went from twenty to thirty ounces. As I cleaned and crushed my first five lump samples, no silver previously worked into the sack could have materially increased the assay of the big pieces, but when once crushed the salting could be easily effected, and, as before mentioned, my small crushed samples were got at afterwards independently. The two lump samples were doubtless given an extra dose before shipment to allow for loss, and my assistant in crushing them doubtless emptied the whole sacks into the crusher, perhaps even shaking them afterwards. There is not the least possible doubt as to the method of salting, because I found afterwards in every sample, by panning and the use of a microscope, that the value lay in the fine metallic silver which did not exist in the mine itself at all.

The presence of the metallic silver in the samples was discovered by me in course of milling tests, and its peculiar character so far raised suspicions as to lead me to endeavor to get a new sampling; but I was defeated by a concatenation of circumstances too involved for explanation here; and chiefly due to the skillful manipulation of the gang, who, with every appearance of willingness to help in any way, managed to block every step. In this course they were assisted by my principals, who pushed on for completion of purchase, and would not hear of any chance of error in view of previous reports by other engineers, and of the necessity of making payments at a fixed date. Nevertheless, within a few days of the completion of the purchase I sampled the mine again; the first assays settled the matter, and I cabled the fact of the whole business being a swindle to the purchasers, and started on the uphill work of bringing the matter home to the gang. Now salting is not a thing which a man does by the roadside while his neighbors are going to church; and unless one of the conspirators should "peach," it is always very difficult to make an absolute case for trial. Owing, however, to the form of "salt" introduced into my sacks, which I was able to separate and exhibit by microscope slides, and to a vast amount of circumstantial and detective evidence collected little by little, I was able, after four years of working and fighting, to get a sweeping judgment against the vendors of the mine. Of the three "honorable gentlemen" who were principally interested in the swindle, one was Mayor of a flourishing town, who has, since the judgment, disappeared from view. Another, who did the scientific part of the work, is, I believe, enjoying a position of political trust in his country; for, in a free and progressive country, under Irish rule, the personal misfortune of being found out and convicted does not spoil a citizen's political career.

From facts and evidence in this case I am able to throw some light, not only on my own shortcomings, but on the misfortunes of three other engineers in respect to this same property, all useful here for the purpose of showing variations in the art of salting. The English engineer had not even sealed his samples, but had tied his sacks with string, and had crushed and sampled the ore in a local mill before shipping to me. Before this, however, the gang had been able to calmly empty out his average samples and fill his sacks with the best selected ore of the mine, so that no introduction of foreign matter was necessary. In my milling tests on his samples I had made no microscopic examination as I did later on my own sampling; and when I found the metallic silver (which I supposed to be native silver, but was still suspicious of) I at once looked for the previous assay samples of a year before. Had I been able then to find these the game would have been up; but here, as at one or two other turning points in the case, it is clear that the devil had a retaining fee from the other side, and was earning it. We usually kept small assay samples of all tests for a year, and then threw them away, and the last cleaning out had been down to and inclusive of the indentical samples I wanted. Curiously enough, some months afterwards a single sealed bottle of the mixed average of all the samples of the English engineer was found, and made useful evidence in the case, for it contained none of the metallic silver which constituted the value of my samples.

An American mining man who took small samples and sealed them with the end of his pen-knife, as a distinguishing mark, took the samples himself to the Express Company's office at the nearest railway station, but the agent of the Express Company had been persuaded to let the owners of the mine take a look at these sacks of ore in his charge. They opened the sacks, changed the ore, and resealed the packages, using a pen-knife, as the expert had done.

The experienced western engineer—whose report had been received by me before I first went to the mine—had taken his samples carefully, quartered them down in the mine to small samples, put them in sacks, and sealed them with his own seal, having his initial on it. He also delivered his samples personally to the Express Company, and felt safe in consequence. At midnight, two of the salting gang and the Express Company's agent were at work on these sacks. To avoid breaking the seals, which they could not duplicate, they opened the sacks from the bottom, at the joining, and neatly sewed them up again after substituting a more satisfactory grade of ore than mere average samples of the mine were likely to prove. A sack which has the sewing of the joining inside, and is sealed at the mouth, cannot be opened at the bottom and re-sewed with absolute impunity; but the opening need not be large, and with neat work, and the big chances of the expert having absolute confidence in the Express Company or post office, after he has personally delivered his samples, the business can be done. It certainly succeeded in this instance up to the salter's full expectations. The enterprising gentleman who was directing operations, evidently thought, however, that cutting seams of sacks and re-sewing was more fatiguing and not so artistic as duplicating seals, because he had the foresight to take a copy of the impression of the seal on the sacks, and get one made for himself. The expert's initial was not his, but he explained to his friends that it might come in useful some day.

Besides these three experts and myself, there had previously been a professor of geology who had made a good report, on which a company had been formed, the mine purchased, and some working capital raised. It took this company some time to find out what sort of a property had been secured, because the head of the gang had bargained to be retained as manager. He judiciously steered the business into debt, after getting all the cash forthcoming for working, then sold the whole property out for a song to one of his confederates, and started out on the search for fresh "suckers." I don't know how the professor was had, but probably he was occupied in the more important geological questions in connection with the deposit, and asked the vendors to get him some good, fair, average samples by which to determine the value.

The microscope or a very strong glass is often of great service, as shown in the foregoing case. In silver ores the silver-bearing minerals can often be washed out and identified, and with gold ores the color and form of the metallic particles are sometimes suggestive. Once in Dakota I was taken to see a vein said to be rich in silver, but the appearance of the vein matter raised an immediate doubt as to what form the silver could be concealed in. By panning I obtained some native silver, but when examined under a glass some of the pieces showed traces of native copper attached. The only place I know where native silver and copper occur actually welded together is the copper region of Lake Superior; and on questioning a little the honest miner who was my guide—and who kindly assisted in crushing some samples—I found he had formerly worked on Lake Superior. No great intellectual effort was then necessary to account for the occurrence of the silver in the very unpromising looking vein matter.

In the case of panning tests on gold ore, or gravel, or for precious stones, it is of course comparatively easy for any one who is allowed to be within a short distance of the expert to get in his salting work, and solitude is the only protection. Among the known methods worth a passing mention are the following: The salter may use a quill toothpick as a weapon for long-range shooting, or have gold dust in his nails for short range, or charge his pipe or cigar and not watch where the ashes fall. Cases have been known of gold pans prepared in advance by a valuable varnish which gradually rubbed off in use. Probably some of our members can describe other varieties of means for reaching the same end; and although it is not possible to mention all the devices, there may be some utility in putting on record for others the better known ones, for it is certain that many young engineers start out with confidence of much learning, ready to undertake responsible examinations, and without any clear idea of the dangers they are courting. A man may acquire a fair amount of practical experience, and confidence begotten of the same, without happening to get into surroundings of any real danger, and so when least expecting it may yet be nipped. All men of experience agree that the only absolute protection is solitude, and that trusting to knowledge of the old tricks or to personal watchfulness is quite insufficient if any person is immediately around.

*Paper read on Dec. 19, 1894, at the meeting of the Institute of Mining and Metallurgy.

The Panama Canal.

The great De Lesseps Panama ditch is a melancholy wreck. The wharves are falling into the water and acres of machinery are rusting to dissolution. On the isthmus are nearly 1000 miles of steel track with locomotives and thousands of dump-carts, now half hidden in the tropical growth. Seventy-six great steam shovels stand side by side in the excavation buried in luxuriant vegetation, so that only the gaunt arms stand up above the green. While 200 locomotives have been housed, it is estimated that nine-tenths of the millions squandered on this prodigious enterprise is going to waste. Much of the excavated land has been washed back into its original place, and the great scar on the face of the Panama isthmus is rapidly fading from view.

Along the Colorado River.

To the Editor:—To one who has never examined or even seen the mines bordering on the Colorado river from Yuma to the Needles, they are a revelation. Some time since, while at the San Xavier in Tucson, Arizona, a very prominent mining engineer, knowing that I was interested in mining, asked me if I had ever been along the Colorado. "If not," said he, "do not go back to New York until you have seen that wonderfully rich country in gold, silver, lead and iron." Tin had not then been discovered in any quantity, said he. I have spent several weeks in a careful examination of the different mining districts, and as a result I can say that within the next five years the country between Ehrenberg and Yuma will surprise the world in its output of gold, silver and lead. Copper does not amount to anything, but iron, manganese, zinc and other minerals will come in time, when cheap transportation and living can be had. The great cement belt of gold east of Ehrenberg, the gold veins nearer the river, the great gold veins at Picacho—the finest free-milling belt of gold ores I have ever seen, together with those farther back from the Colorado, will astonish us all, while the rich silver and lead districts of Castle Dome, Eureka and Silver districts will open the eyes of our silver-producing sections. Just at present but little can be done on account of the high cost of provisions and the exorbitant rates of freight. Think of it! Five cents per pound for beans, potatoes, flour, barley, or oats; $23 to $30 per ton for hay; $40 to $50 per thousand feet of lumber; eight cents for onions and ten cents for all other vegetables; twenty to twenty-five cents for bacon, ham and lard; fifteen cents for sugar; fifty cents for coffee. In these times the miners cannot stand it and live. But the grand keynote has been struck by a company of wealthy capitalists, whose names are purposely withheld from the public at present, who have at Barrier Rocks on the Colorado river, near Picacho, a large millsite for water power for the largest electric plant ever constructed. The river at this point is divided into four channels or waterways by great piers of rock thirty-five to seventy feet above the river and having a base of from 100 to 500 feet square, being 75 to 125 feet apart and extend out into and down the river far enough to give room for the construction of from 100 to 150 distinct water wheels which can be built so that they will stand in lines or series of three or four each, on one or different shafts in line. At first, one wheel or a series of wheels will be put in and be connected to a 1000-kilowatt generator, the largest ever built. Lines will be put up first to the mines and mills which, by the time the wheels are ready, will be in operation. Then, as fast as the demand increases, other wheels or series of wheels will be put in. These wheels will be suspended or hung from iron or steel bridges which will rest on the great piers which Nature has already constructed. The entire work will be of iron, steel and aluminum. In short, the plan is this: To furnish power and light for running all the mines, mills, furnaces, smelters and reduction works within a radius of 100 miles; to run a narrow guage railroad which will be built to connect the mines and mining plants with each other; to run steamers from the Needles to Yuma and the Gulf; to pump water for irrigating all the valleys along the Colorado, and also into the canals that will be built to irrigate the great valley of Colorado below but adjacent to Yuma; to supply power to every manufacturing industry, to every farmer, fruit grower and mechanic who may want it and who shall settle along any of the lines of the plant within 160 miles of the main station. Will it be done? Yes, sir; and within the next five years, mark my words. Do you know, within the area named there are at least 1000 good mines that will furnish ore for nearly 10,000 stamps or their equivalent in crushers, smelters and other reducing appliances; and that from 40,000 to 50,000 horse power can be developed at Picacho and Barrier Rocks. There is no other such a place on the Colorado, at least below the Needles. While at Picacho I found that it cost the great English pumping plant $132 per day for wood alone, not counting the handling of it. The electric company will furnish the same power for $16 per day. No wonder the pumps are idle at the present time. "Yes," said he, "you will see all this done, and the greatest mineral belts in the world put to production." I wondered. I started as soon as I could. I have spent weeks in the careful examination of that grand mineral section. All he told me is true. Castle Dome takes the lead for lead and silver; Silver district for silver, but Picacho and Ehrenberg for their free-milling gold ores—the former for its immense veins 20 to 100 feet wide and the latter for its cement belt, which pays from $6 to $10 to the mill and can now be mined and milled for $1.10 per ton in a thirty-stamp mill, but will be done for forty-eight cents per ton when the electric plant gets to work. This, of course, is in large mills. Barrier Rocks is a wonderful place. It could hardly be better adapted for its work if built expressly for the great electric plant which will soon crown its summit. The opening up of these vast regions is only a question of time. Moneyed and mining men, experts and mining engineers from Montana, Idaho, Colorado and the Dakotas are quietly coming into these sections, carefully examining the mines and minerals, getting the price of properties and reporting to their principals, and in all I have met I have found but one man, a Montana bloater who did all of his prospecting in a boat with a well-filled demijohn, claiming that he was sent here by all the millionaires in Montana, and he condemned everything, yet tried to get a bond on one of the best mines on the river. Before I go I may report again. You can rely upon this section on the Colorado coming out all right in a little time.

Ehrenberg, Ariz., Jan. 8, 1896. Engineer.

As to Mr. Silberstein's Theories.

To the Editor:—Your editorial "Not Proven" in to-day's paper is very well headed. You make Mr. Silberstein father every man's theory as well as his own, and, as stated therein, he is this, that, or the other. You will please allow me to correct your premise from which you drew your conclusions. In the center of the article referred to, you quote Mr. Silberstein as follows, which is correct: "Motion is actually inherent in the planets themselves, as in every substance or body existing in the universe." What follows is not his belief at all, but Newton's, and similar beliefs. Mr. Silberstein, in the article you criticise, was stated to have said there are only *two* possible causes that would explain the constant motion of the planets and wherein lies the propelling force: First, as stated above—which is Silberstein's; and, second—which is Newton's and his followers, and which, in your editorial, you impute to Silberstein, viz: That motion was originally produced and is still being produced by a force outside of the planets; that a body has not a natural motion in it, and when it moves, the motion must have been produced by a force outside of it.

You will notice that this puts quite a different phase to the question, and is clean cut. In either case, the motion of the planets, as established by Kepler, cannot be explained by Newton's principles.

Mr. Silberstein believes the original atom had a double force, originated by radiation from the center of its sphere, necessitating its elliptical path; and when joined in combination with other atoms in their afterwards concrete form, its motion and velocity increased according to its mass centrality of motion generating and accelerating during its planetary potentiality. Consequently, it is as impossible to believe a planet was sent into existence "full fledged" as it is to believe man was suddenly thrown into existence full fledged, with all his faculties matured, mentally and physically. If Kepler, by mathematical calculation, correctly inferred what the motion of the planets must be, may not the philosophies of the Law of Evolution to-day infer from its application on known things on the earth what might necessarily be the planetary condition of the earth in its formative stages?

San Francisco, Jan. 19, '95. E. W. Keeler.

[The above is gladly given space, for the theme touches upon most interesting topics of discussion. The Press must be pardoned for having honest doubts regarding the solidity of the scientific strata on which Mr. S's theory rests. It is not a matter of creed nor dogma, and skepticism is allowable to us. It seems advisable to suggest (and the suggestion is made with the humility that accompanies imperfect knowledge) that, in discussion of this particular matter, it is desirable to keep in view the line between pure metaphysics and pure science.—Ed.]

Granite as a Fertilizer.

To the Editor:—In an editorial in to-day's issue, you notice Mr. Hensel's "stone meal" as a soil fertilizer, and it recalled an incident I read about as a result of a similar discussion, which was whether pure granulated granite would sustain vegetation. This person took a flat rock, protecting its edges, and covered it with granulated rock twelve inches deep in which he planted his seed, which matured of its kind in appearance as of ordinary growth, particular pains having been given to keeping it well watered during growth. And in this connection I would speak of an incident mentioned by Prof. Mapes some years ago in New York which came under his own observation, viz., that in a deposit of magnesia, when pulverized, it was found to act as a cathartic of a drastic character. It was afterwards submitted to a trituration of 100 times and became one of the mildest of laxatives. Whether the disintegration of rock by heat, frost, ice and rain has more or less virtue than when reduced by artificial means may not be easy to decide. A proper mixing might do whenever experiment determines its value.

San Francisco, Jan. 19, '95. E. W. Keeler.

The Future of Gold.

In the United States the production of gold has been very uniform since 1887, never varying much from 1,596,375 ounces, or $33,000,000, until 1893, when it amounted to 1,739,323 ounces, or nearly $36,000,000. It is noteworthy also that the gold output of this country in 1893 was the largest since 1880, and came within 1677 ounces, or about $45,000, of equaling the yield of that year. The net increase of the gold output of the United States in 1893 over that of 1892 was $2,940,000. The increase was most noteworthy in Colorado ($2,227,000) and Montana ($684,613). On the other hand, the product of Nevada decreased $613,000, out of a total decrease in six States of $928,785. It is too early yet to state positively what the gold product in the United States was in 1894, but this much is certain, that it will largely exceed that of 1893 and probably reach $43,000,000, an increase of $7,000,000 over that of the latter year.

The tendency of all the gold-producing States is to add to their annual product. The repeal of the purchasing clause of the act of July 14, 1890, has stimulated the search for gold, and a good share of the increased gold output in 1894 will be traceable to it. There are no indications whatever of a falling off in the future of the productiveness of the gold mines of this country, although, considering the rapid growth of the South African production of gold, it is difficult to predict how long the United States will maintain its supremacy as a gold producer. New mines will, of course, be discovered here, but the discovery of such mines is still more likely in Africa. Much will depend on their relative richness. So far as can now be seen, says Director of the Mint Preston, the greatest hope of a largely increased gold product of the United States in the future lies in the removal of all restrictions on hydraulic mining in California. That has already been done to some extent by the so-called Caminetti Act, passed March 3, 1893. If means could be found to remove all restrictions on this class of mining—and that may be a possible achievement—it has been estimated that the deposits in that State would add something like $500,000,000 to the gold stock of the world.

In Australasia the production of gold in 1893 was 53,698 kilograms, representing $35,688,620, against 51,398 kilograms, representing $34,158,966, in 1892, an increase in the former year of 2300 kilograms. In like manner 1892 showed an increase of 4152 kilograms over 1891. Indeed, ever since 1886 it may be said that the gold output of the Australasian colonies has been continuous. The falling off of the yield in 1890 and 1891 from that of 1889 can scarcely be said to have broken the continuity referred to, for both 1892 and 1893 show a marked increase over 1889. The product from alluvial deposits is continually decreasing in Australia, and that from quartz mining increasing. The alluvial deposits yield only about one-third of the total product of Victoria and not five per cent of that of Queensland. On the other hand, "the deep leads," which are only deep alluvial beds, but which must be worked like veins, are far from being exhausted. Thus far they have been operated only to a very limited extent. Moreover, a large number of quartz mines have heretofore been abandoned as soon as the pyrites was reached. There is no reason why work on such mines should not be resumed, with the aid of the newly discovered processes which have proved so successful in South Africa, and with equally successful results. Everything considered, it is to be expected that the production of Australasia will continue to increase at about the present rate at least for an indefinite period.

Russia next claims our attention. Here, too, where the gold yield is almost exclusively from alluvial deposits, the production of that metal has been continuously increasing since 1886, as witness the following figures: 1886, 30,872 kilograms; 1887, 30,232 kilograms; 1888, 32,052 kilograms; 1889, 35,970 kilograms; 1890, 35,296 kilograms; 1891, 35,356 kilograms; 1892, 37,325 kilograms; 1893, 39,804 kilograms. The continuity of this progression is broken only in a single year. It is impossible, however, to venture any prediction as to Russia's output of gold in the future. The circumstances on which it depends are too many—legislation, the price of bread, the seasons, and the course of the paper rouble. Reasoning from analogy, however, one would be inclined to believe that the production of gold in the great empire of eastern Europe would continue to increase for years to come. Again, there is India. Outside of the great producing countries—the United States, Australasia, Russia and South Africa—the increase in the production of gold has nowhere been more rapid: 1886, 20,383 fine ounces; 1887, 15,464; 1888, 32,729; 1889, 72,691; 1890, 96,739; 1891, 120,691; 1892, 160,525; 1893, 184,477. The remaining countries to which I shall direct the attention of the reader are the three Guianas. Their gold yield was as follows: 1887, 1802 kilograms; 1888, 937; 1889, 2348; 1890, 3186; 1891, 5026; 1892, 6185; 1893, 6439.

The production of the world in 1886 was 159,494 kilograms; in 1893 it was 243,006 kilograms; but,

great as was the world's gold output of that year—greater than that of any other year in the world's history—I believe that that of 1894, and of a series of years to come, will be successively and progressively greater, and that what was said by the writer of the world's gold product in 1893 in the Report on the Production of Gold and Silver in that year, will, with the change of a few figures, be true of that series. He there uses these words: "The world's output of gold in 1893 was the largest in history, amounting, as it did, to 234,006 kilograms, of the value in round numbers of $155,522,000."

Meadow Lake Again.

It is reported that "there will be a great rush to the Meadow Lake district when the snow shall have disappeared." 'Tis nearly thirty years since that famous district first attracted public attention.

In 1865 the excitement began. Lots were sold by the California Company "to actual settlers" for $25. In the early part of November, 1865, the majority of the new home seekers, afraid to spend the winter in the Sierras, left for more congenial climes. By the first of December the country was covered with snow to a depth of five feet. The months of March, April and May, 1866, were of unprecedented severity at Meadow Lake. All traces of trails and highways were obliterated by the heavy snowfalls. As an evidence of the character of the storm, it may be stated that from the 20th of May to the 1st of June there was a constant snow.

By the end of June, 1866, there were 4000 people in the newly established town. Everything was excitement and activity. The sole topic of conversation was ledges, stocks and town lots. For a lot 60x80 feet on any of the principal streets from $1500 to $2500 was asked, and in many cases paid. Small tenements rented for $200 per month, and rents everywhere were proportionately high. Lumber cost from $50 to $75 per thousand feet. A stock board, composed of thirty members, was organized. This may be regarded as a unique transaction, considering that there was not a single mine in operation at that time.

During the year four good roads were opened from the town—one leading to Bowman's station, another to Jackson's, a few miles distant; a third to intersect the main Henness road at a point near Truckee Lake; a fourth connected with Cisco, on the Central Pacific railroad, bringing the residents within a day's ride to San Francisco. Eight mills were erected for the reduction of ores, with an aggregate capacity of seventy stamps. The construction of these mills incurred an expenditure of $200,000. Two furnaces for the roasting of ores were built, and Platner's chlorine process was used at one of them. In 1869 Burn's process created some excitement and was the means of spending a large sum of money, but all to no purpose. In 1873 O. Maltman placed some machinery into the U. S. Grant mill for working the sulphurets, but the plan was abandoned.

The winter of 1866–7 was a most severe one, the snow falling to a depth of twenty-five feet. But a large number of the residents enjoyed the pleasure of being thus domiciled, whiling the weary hours by bringing into requisition indoor pastimes of every description. Others endured the hardships and privations in the fond hope of regaining some of the capital they had invested. In this they were doomed to disappointment and despair.

In 1866 the Meadow Lake *Sun* was established by W. B. Lyon, H. G. Rollins and Judge Tilford. During its existence, which lasted only a few months, it earnestly and consistently advocated the superior claims of the town as a "rich metalliferous district." By 1870 Meadow Lake was almost deserted, all that was left being empty structures. On the 27th of September, 1873, a fire originated in the Excelsior hotel, which soon laid the whole town in ruins. Only two houses were left to indicate the spot where once excitement reigned and $2,000,000 were absorbed in laying out this summit city. In the zenith of its prosperity there were twenty saloons and three hotels.

It is estimated that during the summer of 1865 1200 locations were made in the district, containing in the aggregate more than 1,200,000 feet of ledge rock. In the excitement which prevailed locations were made all over the country. Bowlders, masses of granite, rocks of every description assumed to the distempered fancy of the prospectors the shape and outlines of a quartz ledge, and were duly entered upon the Recorder's books. The ledges, lying even with the masses of granite around them and capped with a species of mineral which is not pure quartz or country rock, are traceable by broad stains of a dark, reddish hue. Under the circumstances it is not at all surprising that parties whose attention and efforts were directed to other purposes than search for gold should have failed to discover the existence of treasures so strongly concealed by nature. During its short career some thirty mines were developed to a depth ranging from 30 to 240 feet. It is to be hoped '95 will prove more satisfactory to the treasure seekers at Meadow Lake.

The Manufacture of Aluminum.

The suit between the Pittsburg Reduction Company, owners of the Hall patent, and the Cowles Electric Smelting and Aluminum Company, was recently decided by Judge Taft, United States Circuit Court, Ohio, in favor of the Pittsburg company. The judge in his decision gives the following regarding the Hall electric process for making aluminum:

Electrolysis is a process for separating a chemical compound into its elements by passing through it an electric current. The current is effective for this purpose only when the compound is reduced to a liquid state, either by solution or fusion. The compound, which is decomposed by the current, is called the "electrolyte."

Aluminum is a metal which was first isolated by Wohler in 1827. There is great difficulty in obtaining the pure metal from its compounds, because of the tenacity with which it unites with other substances. The compounds of aluminum are very abundant in nature. The most common, perhaps, is the oxide of aluminum, called "alumina," one molecule of which is composed of three atoms of oxygen and two atoms of aluminum. Alumina is insoluble in water and practically infusible.

Fluorine unites with the metals to form fluorides. The fluoride of sodium and the fluoride of aluminum, united, form what is known as the "double" fluoride of aluminum and sodium. There are several minerals found in nature which are double fluorides of aluminum and sodium, of which cryolite is much more common than the others, and is found in large quantities in Greenland. Its uses are so extensive that it has become a well-known article of commerce.

More than fifty metals are known to chemists. When one of these is united with non-metallic substances, and the compound is reduced to a liquid state by solution or fusion, and subjected to an electric current which decomposes it, the non-metallic element of the compound will be drawn by the current to that point in the bath where the current enters it from the positive pole, called the "anode," and the metal will move in the direction of the point where the current leaves the bath for the negative pole, called the "cathode." Metals differ, however, in the ease with which the current can draw them to the cathode, and when one is more sluggish than the other in yielding to this influence, the one is said to be more electropositive than another. Scientists have arranged all known metals accordingly.

The only metals more electropositive than aluminum are magnesium, calcium, strontium, barium, lithium, sodium, potassium, rubidium and caesium. All other metals yield more readily to the current. When several compounds in solution or fusion are electrolyzed, the current will attack and decompose that compound whose parts are least firmly united, or, as the phrase is, which is least stable. As might be supposed from the foregoing, the more electropositive a metal is, the more stable its compounds are likely to be. Alumina is so common in nature that every one, in a desire to get pure aluminum, would naturally turn to that as one of the simplest of its compounds; but the fact that the oxygen has proved to be so firmly united to the aluminum as to resist the action of the highest heat, has been very discouraging to chemists. Hall, the original patentee of the patent in suit, was a resident of Oberlin, Ohio, and a graduate of the college of that place. He had a strong taste for chemistry, and after leaving college, in 1835, gave his attention, among other things, to the aluminum problem, which had baffled so many before him. He conceived the idea of obtaining aluminum from alumina by electrolysis, and concluded that, if he could find a bath made up of compounds more electrically stable than alumina, which would freely dissolve alumina, the application of the current to the mixture would precipitate the aluminum upon the cathode, and would free the oxygen at the anode. He discovered that the fluoride of aluminum, when united with the fluoride of any metal more electropositive than aluminum to form a double fluoride, would, when heated to fusion, dissolve alumina as freely as sugar will dissolve in water, and that an electric current passed through the fused mixture would deposit pure aluminum at the poles. Hall took out one patent for the process, in which he used a double fluoride of sodium and aluminum, and in this patent he also claimed the general process broadly, as we have stated it above. This is the patent in suit. He also took out other patents, as permitted by the practice of the Patent Office, covering the process when the fluorides or other metals more electropositive than aluminum are used.

The two claims of the patent in suit which are here involved are:

1. As an improvement in the art of manufacturing aluminum, the herein-described process, which consists in dissolving alumina in a fused bath composed of the fluorides of aluminum, and a metal more electropositive than aluminum, and then passing an electric current through the fused mass, substantially as set forth.

2. As an improvement in the art of manufacturing aluminum, the herein-described process, which consists in dissolving alumina in a fused bath composed of the fluorides of aluminum and sodium, and then passing an electric current, by means of a carbonaceous anode, through the fused mass, substantially as set forth.

The Management Criticised.

To the Editor:—I've had the pleasure of reading an article in your paper in the defense of miners. It is the nicest article I ever read and to the point. I wish you would also write up something of the same kind in defense of the mechanical engineers: those who served their time legitimately, before going out to run engines, and have to compete with those stoppers and starters, sage-brush engineers, who know just enough to stop and start an engine and carry steam, and in a very knowing way talk engine to the *expert* superintendent, who, as a rule, knows less about an engine than they do, except in a saloon or card-room. Here and New Mexico are the worst places I was ever in for that. For instance, a superintendent will come into town, and he wants to hire an engineer (he means engine runner or fireman runner). He finds one, and says: "Do you want a job running engine?" "Where?" "Seventy-five miles from here." "What do you pay?" "Four dollars (sometimes $3.50). You can come out on the stage." "All right, I'll be out there." Now comes expense: $12 stage fare, $30 for bedding, etc. When you get out there, you find the accommodations are not fit for Chinamen or Hungarians. In bunk-house or boarding-house there is no distinction between engineers and common laborers. Mexicans, Indians, Hungarians and white men all jostle against each other, and their behavior is like so many hogs in the dining-room or sleeping place. After you're there two or three days there's no wood wheeled up for you. You inquire the cause: the superintendent is going to town, the wood wheeler is going to hitch up his team, so there's nothing else to do but to wheel wood or stop the mill. The engineer takes the situation in at a glance, doesn't want to make a kick till he has at least made expenses, and, like the burro, grins and stands the abuse. The next day the wood wheeler isn't there. Cause: the car runner is sick and he must take his place. The old man (the boss) says you must wheel your own wood. So they have virtually rung in another's work on the engineer. In a few days Mr. Superintendent wants to know how much wood you are burning. You measure it up, and find you are using just three cords, $18. "Ah, that's quite a lot of wood, isn't it, for the work we have to do (ten stamps, four concentrators, one rock breaker). I wish you would overhaul that engine and see if you can't improve on that." (Nothing said about improvements or saving when hired in town.) I go to work and make a change on the engine and save a cord of wood, $6. Do I get anything for it, or for knowing more than a fireman runner? No, not even thanks. Now, sir, why shouldn't a mechanic be paid for his brains as well as a doctor or a lawyer? The only reason I can assign is because the expert superintendents (who perhaps were preachers in Cornwall or Colorado) don't know the difference between good men and indifferent ones, and they themselves reap the benefit of your knowledge and saving. Does the company? Is it any use for a man to go into a shop to learn a trade (from boyhood to manhood) and find when he leaves the shop that he has to compete with stoppers and starters, who know much with their mouths and but little with their hands?

I was in the Vulcan Iron Works in Pete Torquet and Joe Moore's time. I claim to be the originator of the Young Mechanics' Evening Drawing School, going in my overalls at noon to one of the Board of Education, to see if he wouldn't meet with the Legislature and try to get an appropriation for that special purpose. At that time about a dozen of us apprentices used to meet in one of your old printing rooms, on Clay street, between Sansome and Battery, and a draughtsman from one of our shops taught us five nights in a week. We afterwards moved to one of the rooms in Lincoln school, which was quite a distance to pack a large drawing-board and instruments, and the scholars fell off in consequence. About that time business in the shops got very slack and I steered for the mountains, where I've been almost continuously.

Engineer and Machinist.

Lynx Creek, Yavapai Co., Arizona.

B. C. Brown, of Kingsley, Or., suggests that there might be economy in having inserted teeth in crosscut saws, as well as circular saws. It would seem so at first. But while a circular saw (made for inserted teeth) would cost from $50 to $100, and a new set of teeth only $1.50 (perhaps), the ordinary crosscut saw (certain dealers and manufacturers say) costs but little if anything more than the teeth would. The scheme would work, but they say it wouldn't pay.

Lord Kelvin says that the internal heat of the earth has nothing to do with climates. The earth, he thinks, might be of the temperature of white-hot iron 2000 feet below the surface, or at the freezing point 50 feet below without at all affecting a climate.

The Mineral Hydrocarbons.

Their History, Geography, Geology, Physical and Chemical Properties and Uses.

NUMBER XVIV.

Written for the MINING AND SCIENTIFIC PRESS and copyrighted 1894, by Henry G. Hanks, F. G. S.

1866.—Mr. Charles Stott began work on Santa Paula creek, Ojia ranch, eighteen miles east of Ventura, Ventura Co., at the base of Sulphur mountain, and erected a refinery on a small scale. He made several thousand gallons of illuminating oil, and then gave up the enterprise because it did not pay. October 22d the San Francisco *Alta* published an article on petroleum and refineries, giviug Chas. Stott the credit of refiniug the first oil in the State.

In this year there were two refineries established in San Francisco, one owned by Hayward & Coleman, the other by Stanford Bros. Neither of these establishments achieved any considerable success, and were eventually abandoned.

Mr. Polhemus, also, had a refinery at Los Angeles. A portion of the crude oil which he refined was obtained from the wells near the town of Los Angeles, aud some was hauled by teams from Pico canyon.

Mr. Hughes bored for oil in Pico canyon and struck a flowing well at 140 feet, but the tools became fast and could not be extricated.

A well was sunk on the Potrero iu San Francisco, but the result was not satisfactory. There was considerable excitement about oil during this year.

The "Pioneer Petroleum and Refining Co.," of San Francisco, was incorporated. Chas. Stott, David Hunter aud H. P. Wakelee, trustees.

Chas. Stott had a refinery, corner Chestnut and Taylor streets, San Francisco.

The Adams well, near Mt. Diablo, in Contra Costa county, in a second shaft at a depth of 100 feet, encouraging indications of oil were met with, and at 125 feet the drillers encountered hard rock, beneath which they found a stratum of oil from which five barrels were pumped in two days.

In Santa Cruz county the Petroleum Oil Company put up retorts for refining their oil, which produced 200 gallons three times a week.

In Colusa county a well was suuk, 460 feet in depth. At 50 feet a stratum of thick oil (maltha) was met with, another at 112 feet and a third at 117 feet. The well filled up with salt water, through which bubbles of gas arose, sometimes with violence sufficient to throw water out of the well. This well was situated at Oil Center, six miles east of Sulphur creek.

In Humboldt county, work was discontinued on Mattole creek. The "North Fork" well was down 230 feet; at 207 feet oil was struck, which continued. The following are the names of the most important wells in the county at that time: Jeffries, Joel Flat, Upper Mattole, aud Irwin Davis. The latter was down 655 feet aud had oil in coarse sandstone.

The Buena Vista Oil Company of Tulare Co. (uow Kern) was specially active during this year; and while work was subsequently suspended, it is now known that the deposits have very considerable prospective value, which in the near future is likely to be realized. The oil claims comprised some 1200 or 1600 acres on the west side of Tulare valley. The exact locality was sections 19, 20 and 29, township 30 south and range 22 east and sections 12 and 13, range 21 east, San Bernardino base and meridian. The compauy set a still with a daily capacity of 300 gallons near a large spriug of good water, three miles from the oil springs. The company attempted to sink a well for water in a more convenient location, but did not succeed in finding it. For thirty feet or more the formation was alternate layers of shale, sand and asphaltum; below thirty feet a three-foot stratum of asphaltum was met with, very difficult to penetrate, but no water. Two adobe buildings were erected—one for the workmen and one at the refinery.

Iu 1865 Mr. Stephen Boud and Mr. E. Benoist commenced a well on the flat below the tar springs on the company's claim. At a depth of eighteen feet, in raising the auger, the workmen turned it the wrong way and unscrewed the bit, which accident put an end to the work. The company's refining works were under the management of Mr. W. O. Sleeper, from whom I obtained information as to mode of operations. The crude oil was taken from pits or shafts sunk from sixteen to eighteen feet deep. There were also several natural shallow basins or ponds, which, when emptied, soon filled again with maltha and water. At the bottom of the artificial pits a quicksand of oil, water and saud was met with, which could not be overcome by curbing or otherwise controlled. An open cut was then made into the hill, but a solid ledge or bed of sandstone and thick beds of asphaltum were met with. This cut was from seven to eight feet deep and four feet wide, from which some maltha was obtained and distilled. At one time it was thought that from the shafts aud open cut five to eight barrels per day could be collected. Oil from the surface had a density of 10° to 12° Beaume; at the depth of ten feet, 12° to 14°; and at thirty feet the oil was as light as 21°. Three hundred gallons of crude maltha were pumped from the oil wells each day, which was renewed the uext. One hundred gallons of this material yielded by actual working: Buruing oil, 35 gals.; lubricating oil, 45 gals.; residue (mostly coke), 20 gals. Three or four thousand gallons of refined oil were produced in the distillations. The following results were obtained: First run, 5% to 7%, from 47° to 43°; second run, 40%, from 40° to 30°; third run, 35% to 40%, with a density of 30° to 16°. The residue iu the still was soft asphaltum, which, while hot, could be drawn off without difficulty. Many obstacles were met with by the compauy which caused the work to be abandoned. Freights were high, being $60 to $70 per ton to San Luis Obispo and from $15 to $20 more to San Francisco. The nearest fuel or lumber was the forests on mountains thirty miles south. In October a newspaper stated that the Buena Vista Co. had produced 300 gallons of heavy lubricating oil from black oil. The following are extracts from the report of E. Benoist to the company:

After spending some time in viewing the location selected by you, I erected the machinery for the purpose of horing. Within a few feet of the surface, I found the quality to show 12°, and at fifty feet the gauge showed 20°, which is really better than calculated at twice that depth. The oil at this depth is of a greenish hue; and judging from the quality, I did not hesitate to say that, in seventy-five or eighty feet, oil can be produced to reach a standard of 25°. From the general appearance of the surface and the ground through which the boring was done, I feel assured that it is favorable for work at a great depth; but from the easy flow acquired at fifty feet, a number of wells could he made at that depth to produce 50,000 gallons per day at a small expense.

Had the requisite machinery heen at hand, I should have gone to a greater depth, hut deemed it advisahle not to do so at this time, as the quantity of gas issuing would make it difficult to prevent ignition of the oil, which circumstance in your case, where it is so abundant, would entail serious loss. The remedy is simple and inexpensive for prevention in such cases provided you have the material at hand.

This oil is entirely free from any water, salt or other impurity and is very limpid.

I have in transit 100 gallons of crude oil from which I shall make samples of light and lubricating oil upon my return to San Francisco, for inspection by any parties who wish to satisfy themselves in regard to its quality.

I have also discovered, in connection with the oil, a vast bed of what is called Albertine coal, hut I will call it concentrated oil. Thousands of tons of this material can be easily extracted and will he valuahle for fuel for steamers and also for the manufacture of gas. (This mineral described hy Mr. Benoist was undouhtedly crude brea, which is ahundant, as I know hy personal examination at the locality.) There is also a large amount of natural coke, formed hy underground fire, which I put to a practical test by using for fuel with the most satisfactory result.

There are large quantities of the crude oil of a superior quality of that from which I made samples for exhihition at the Mechanics' Institute, and for which the first premium in Septemher last was awarded to the Buena Vista Petroleum Company for hoth light and luhricating oil.

(To be Continued.)

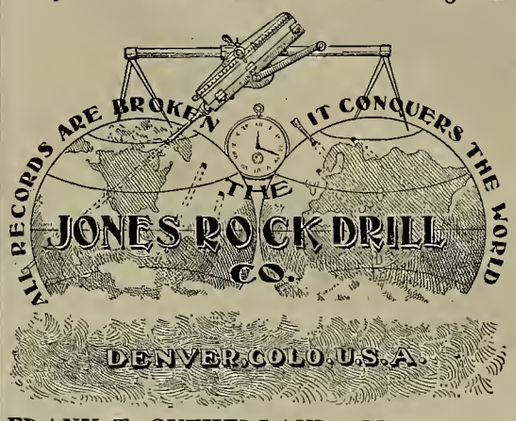
THE JONES ROCK DRILL

IS THE

Only Successful Hand Power Drilling Machine Ever Invented.



It is strong, durahle, reliahle, simple, compact, light, easily handled and operated hy one man, and will reduce the cost of rock drilling at least Fifty per cent.

Our handsomely illustrated pocket catalogue fully explains the features and workings of the drill. It should be in the hands of every mine owner, leaser, contractor and prospector in the West. *Sent free on application.*

If you are interested in Rock Drilling Correspond with us.

WE CAN SAVE YOU MONEY.

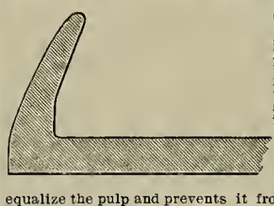
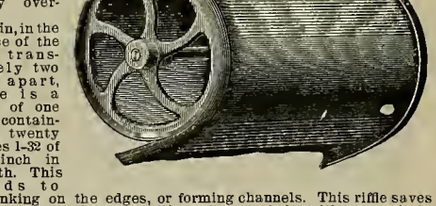
IMPROVED GOLD STAMP MILLS.

General Mining Machinery and Supplies.

Blasdel Improved Concentrating Belt.

We keep in stock helts suitahle for the Frue, Triumph, Johnston and Tullock machines, and make all lengths and widths to order.





Practical mill men must see at a glance the advantage of our helts over any other. First, the flanges stand at an acute angle toward the center, therefore readily conform to the change of direction while passing over the end rollers. Thus the vexation and loss occasioned hy the frequent hreaking of the flanges, as is the case with the old Style, is practically overcome.

Again, in the surface of the helt transversely two feet apart, there is a space of one inch, containing twenty riffles 1-32 of an inch in depth. This tends to equalize the pulp and prevents it from banking on the edges, or forming channels. This riffle saves fine sulphurets and quicksilver that would escape with the tailings from a helt with an entirely smooth surface.

Mechanical Progress.

Internal Rusting of Boilers.

In a recent German paper on this subject the causes of rusting are first considered, the most important being the introduction of air with the feed water. By placing the feed pipe so that the feed water enters the boiler near the low water level, and thus meets the hottest layers of water, the air is quickly exploded and passes out of the boiler with the steam, unless pockets exist in which it can accumulate. Such pockets are sure to rust rapidly, and it is recommended that they should be covered internally with a protecting paint or filled up with cement, provided they are not subjected to external heating. It is also recommended that the feeding should be complete before the withdrawal ceases for a day, in order that the water left standing in the boiler over night may be as free from air as possible. An efficient circulation is also a means of preventing rusting, as it hinders the formation of air bubbles on the shell, which, if they remain clinging to it, cause rusting. The author is of the opinion that faulty construction is more often the cause of internal rusting than unfavorable conditions of working, and summarizes the means of preventing rusting as follows:

First, while the boiler is working: (1) removing air from the feed water before it enters the boiler; (2) removing air from the water while in the boiler, and preventing its accumulation in pockets, etc.; (3) addition of chemicals to the feed water; (4) protective coatings applied to the inside of the shell. Second, while the boiler is standing idle: (1) removing all moisture from the boiler, (*a*) by blowing it off while hot, (*b*) by producing an air current through it, (*c*) by placing hygroscopic bodies inside; (2) direct protection of the shells by painting with tar, varnish, etc., by covering with protective paints and such an alkaline coating as milk of lime; (3) protecting the shells from the varying temperatures by keeping the draft in the flues constant, so as to prevent moisture alternately depositing and evaporating on the shell; (4) protecting the shell by completely filling the boiler with water from which all air has been expelled.

Of Value to Boiler Users.

A drain tap should be fixed in every branch steam pipe, as well as in every main steam pipe which is so laid as to allow water to accumulate therein.

A water-gauge tap fixed to the front of the boiler, on a level with the top of the furnace crowns, would help a boiler attendant, in case of shortness of water, to determine whether it was safe to draw the fires and turn on the feed.

A low-water safety valve would give warning in the event of shortness of water in time to prevent danger.

The feed should be delivered well behind the fire bridge.

A Promising Experiment.

In San Francisco, says the *Engineer and Contractor*, there is being constructed at present a very substantial appearing street railroad track. Ties are laid as in ordinary work, and earth and fine broken stone rammed in between until flush with their tops. The rail is a Z rail, but inclined inward in the manner of a slot rail. About every six or eight feet a bar is bolted to the rails to preserve the gauge. Upon the top of the ties and the surface formed by the rammed earth is laid five inches of concrete brought to a smooth, true curve on top, with a crown of about one inch. Upon this is laid one inch of sand, and then the paving blocks are put in. These blocks are nearly cubical and are soaked in hot coal tar. The blocks on the inside next the rail are shaped to permit the flange of the wheel to travel, and all the blocks are so laid in use there are no wide joints. The completed and viewed at a little distance has the appearance of an asphaltum pavement. The whole effect is very pleasing, and vehicles can cross the track at any angle without twisting the wheels. The road is being built by the Southern Pacific Company for a trolley line and it is understood is a trial of a new patent, the inventor being under heavy bonds for construction and repairs for some period of time. At present one block has been built on Twenty-second street, between Valencia and Mission streets.

Comparative Fuel Value of Coal, Oil and Gas.

Experiments made by the National Transit Company show the following to be the comparative fuel value of coal, oil and gas in the best practice, with boilers of proper construction and proportioned to the work:

One pound of coal will evaporate ten pounds of water at 212° atmospheric pressure.

One pound of oil will evaporate sixteen pounds of water at 212° atmospheric pressure.

One pound of natural gas will evaporate twenty pounds of water at 212° atmospheric pressure.

One pound of coal will equal 11.225 cubic feet natural gas.

Two thousand pounds (one ton) will equal 22,450 cubic feet natural gas.

One pound of oil will equal eighteen cubic feet natural gas.

One barrel (forty-two gallons) will equal 5310 cubic feet natural gas.

One thousand one hundred and twenty-five cubic feet natural gas will evaporate one pound of water.

One cubic foot natural gas will equal 860 B. H. U.

One thousand cubic feet natural gas will equal 860,000 B. H. U.

One ton of coal will equal 19,307,000 B. H. U.

One barrel of oil will equal 4,566,600 B. H. U.

In ordinary practice about twice as much fuel is required to do this amount of evaporation.

Varied Uses of Electricity.

According to the account given by a correspondent of the *Engineering Magazine*, Great Falls, Mont., appears fairly entitled to the distinction of being called the Electric City. At Black Eagle Falls, three miles above the town, an immense dam has been thrown across the Missouri, and hydraulic works and power houses erected. Not only are the street cars propelled and lighted by electricity from the power houses, but they are heated as well by electric radiators placed in each car. Elevators, printing presses, cranes and all kinds of machinery are operated by the ubiquitous force. There are automatic excavators, electric pumps and electric rock crushers. A not uncommon sight on the streets is a mortar mixer attached to an electric wire leading down from a pole. The restaurants cook by electricity, the butcher employs it to chop his sausage and hamburger, and the grocer to grind his coffee, and so likewise does the tailor to beat his goose. The subtle fluid is a welcome blessing in every home. The housewives run their sewing machines and heat their flatirons by electricity; they bake their cakes in wooden electric cake ovens that can be set away on a shelf, like pasteboard boxes. They have electric boilers and broilers and teakettles. What a singular anomaly when one pauses to think of it—that of broiling steaks and beating flatirons through the instrumentality of a waterfall!

In a paper recently read before the American Institute of Mining Engineers, L. Waldo advanced the opinion that aluminum forms a definite chemical compound with copper. If a crucible containing molten aluminum, and another containing molten copper at little more than red heat, have their contents mixed, the reaction is so intense that the metals are brought to a state of ebullition and the crucible becomes red hot. A billet of aluminum bronze shows no evidence of segregation or variation in composition from one end of it to another. The compound is A l and Cu 4. Aluminum bronze is difficult to cast, as the shrinkage is great and Mr. Waldo's firm have not yet made castings of more than two tons in weight.

To Build a Tunnel for Moving a Library.

A tunnel is to be constructed from the crypt of the Capitol under the east park to the vaults of the great building for the Congressional Library, now in course of construction. The plans for the tunnel have been completed, and work upon it will soon be begun, that it may be finished in season to be used for the transportation of the nearly 1,000,000 books and pamphlets which make up the vast bulk of the library from the old rooms to the new. It is probable that a temporary railway will be laid in the tunnel that cars may be employed to carry a large quantity of books at once.

One of the most remarkable transfers of the kind in the history of libraries was that in Berlin some years ago, when a regiment of soldiers was put to the work, received their burdens, and marched and countermarched under perfect discipline, accomplishing in a short time the vast labor of removal.

It is possible that when the new building is occupied, a pneumatic tube may be laid through the tunnel that Congressmen may immediately receive books which they desire to consult without the trouble and loss of time which would be entailed in going to the library in person or awaiting a trip by a messenger. It is not expected that the work of removal will begin before the spring of 1896.

Ten Miles Above the Earth.

The greatest height ever attained by balloonists who have returned alive to relate the story of their experience was 37,000 feet—upward of seven miles; this by Glaisher and Coxwell. They left Wolverhampton, England, at 2:30 P. M.; September 5, 1892, and during the afternoon reached the enormous altitude recorded above. Balloons have been sent to a greater height than that attained by the Glaisher-Coxwell airship, but they were not accompanied by aeronauts. In the experiments made by Hermite and Besancon at Paris they sent balloons to a height of ten miles. Each balloon was fitted with self-recording instruments. They showed that the temperature at seven and one-half miles was 60° below Fahrenheit's zero, and that the barometer marked only four inches.

Gold and Silver of the World.

According to the last report of the Director of the Mint the estimated amount of gold money in the world is $3,965,900,000, and the estimated amount of silver money $4,055,700,000. This gold and silver money is chiefly distributed as follows:

	Gold.	*Silver.*
United States	$626,600,000	$625,300,000
United Kingdom	550,000,000	112,000,000
France	825,000,000	492,200,000
Germany	825,000,000	215,000,000
Russia	455,000,000	48,000,000
Austria-Hungary	130,000,000	121,000,000
Egypt	120,000,000	15,000,000
Australia	105,000,000	7,000,000
Italy	96,000,000	30,000,000
Japan	80,000,000	88,300,000
India	.....	950,000,000
China	.....	750,000,000

At the annual meeting of the Technical Society on the 18th inst., Mr. Geo. W. Dickie, of the Union Iron Works, was elected president.

GIANT POWDER FUSE CAP FASTENER.

The instrument presented in the above cut is a new and grand little invention; being designed to save life and limb, and innumerable lawsuits, by doing away with the dangerous operation of digging out wet and unexploded loads, where Giant Powder is used in mining. The instrument is made of the finest cast steel, and crimps the cap on the end of the fuse *firmly* and *absolutely water tight*. There is also a Fuse Cutter attached. **Price 75c. each.**

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Butte.

AROUND FORBESTOWN.—At the Gold Bank mine of W. W. Stow, the forty-stamp mill and reduction works are running constantly, as they have been for the past three or four years. From eighty to one hundred men are employed. They are running a mammoth tunnel from below the present mill site to tap the ledge far below the lowest level. This tunnel, when completed, will be 1100 feet in length, and 300 feet have been already cut. The drilling of this tunnel will occupy about two years.

It is confidently expected that the Shakespeare mill will resume full operations in a short time.

At the Denver a force of miners have just been put at work on the ledge, and the mill will soon be in full operation.

Calaveras.

WORK SUSPENDED.—*Echo:* Work has been suspended in the Bishee mine and mill on Smith's Flat for the present, pending the putting in of a new pump in the shaft. The water has increased to such an extent in the mine that a larger pump has become a necessity. As soon as the new pump is in readiness the mine will be freed from water and operations will be resumed.

GRAVEL MINING.—A cleanup was made at the Moyle claim on Balaklava Hill, south of Vallicito, last week, and according to report, the yield amounted to twelve pounds of pure gold.

A cleanup was also made at the Old Stiff claim, in the same locality, which proved highly satisfactory to its owners, Sloan & Rudorff.

Nevada.

THE RED DOG MINING CO.—*Herald:* A company has been formed to develop gravel mines at Red Dog, to be called the Red Dog Mining Company. It will be a close corporation and the owners are John Spaulding of Seigler Springs, Martin Lawrence of Auburn, W. F. Englebright of Nevada City, and J. S. Goodwin, Frank Goding and R. E. Linder of You Bet.

The company has leased all of the South Yuba Water Company's mining ground at Red Dog and vicinity, about 500 acres in all. They have a ten-year leaso.

Mr. Goding is superintendent, and has several men at work now. In the spring a long drift tunnel will be run from Missouri canyon. The new company is to be incorporated.

This ground is all rich, and years ago it paid handsomely when mined by the hydraulic process. They have to drift and ground-sluice now, which is slow work, but the gravel is rich and the new company ought to make something.

Shasta.

Democrat: At the Parsons mine in Oregon gulch the contact between the sandstone and slate was followed some three hundred feet. At present the contact dips at an angle of thirty degrees and shows the richest bed of gravel in northern California. A new shaft will be sunk on the drift three hundred feet deep, through which the gravel will be hoisted. This works a new epoch in drift mining in this county and what was supposed to be a dream has proved a reality.

NEVADA.

Washoe District.

ON THE COMSTOCK.—Dan De Quille: The Consolidated California & Virginia mine continues to look and yield well. The company have just paid a dividend amounting to $54,000, have shipped $35,690.42 to the Carson mint and have on hand at their assay office bullion to the value of $11,500. They had worked last week at the Morgan mill, on the Carson river, 710 tons of ore which averaged $50.24 a ton. They extract from the mine about 350 tons of ore a week. They have a large amount of ore in sight in the mine opened up ready for extraction.

A new drift in the Hale & Norcross mine on the 975 level shows about eighteen inches of good ore. This drift is going south, and may develop a large body of ore. The ore already assays $43.91 a ton.

During the past week the Alta mine yielded forty-five carloads of ore assaying $39.17 a ton.

The Savage last week milled 110 tons of ore that yielded $30.77 a ton.

The Chollar yielded during the past week 144 tons of ore worth $34.50 a ton.

The yield of the Crown Point was 876 tons of gold quartz, averaging $10.30 a ton.

During the past week the Justice mine yielded 120 tons of ore, which was worked at the Washoe mill and yielded $17.08, principally in gold.

Streaks of pay ore are being found to the south on the 450 level of the Potosi.

FERGUSON DISTRICT.—*Tribune:* J. P. Neshit, who for several years past has been operating in Pioche, is now at the Cullen on his way to Europe. Included in his luggage is a sack in which is contained, according to assays, proof of at least one more bonanza, the vaults of which promise good returns to all who invest. Speaking of districts last night, Mr. Nesbit stated that attention was now being largely devoted to the gold prospects and there would be a great deal of active prospecting when warm weather came. The April Fool is making a mark for itself under the lease to Frank Wilson, who is just now shipping a lot of ore to Bullionville. The Magnolia, which is being worked by Ferguson Bros. & Manning, is another promising prospect, as is also the Flagstaff, which latter Mr. Noshit is one of the owners. Referring to Captain De Lamar, the visitor says the machinery for his mill is steadily arriving, and that it will be ready for operation in March. The outlook for the country around Pioche, says Mr. Neshit, is very gratifying, and the gold production of 1895 promises to place the district far up in the list of gold producers.

SILVER STAR DISTRICT.—The Douglass mill of five stamps is running steadily on ore from the various mines. It is a custom mill and it reduces ore in fifty-ton lots at five dollars per ton. The ore is free and the process of reducing it the simplest kind. It is crushed in a battery and run over plates. There are no pans and no use for them.

The principal mines are the Hardscrabble, the New Party, the Oneida, the Direct and Mary. The ore from these mines yields from $60 to $100 at the mill. Besides these there are a dozen or more other mines that yield from $15 to $30 at the mill.

There are about eighty miners in the district, many of whom have leased mines and are making good wages.

Provisions are abundant, but prices are higher than on the railroad. Board is furnished at $1 per day. Wood is abundant, nut pine, which makes excellent fuel grows right over the mines and it sells, delivered at mines, at $5 per cord. There are five good springs of water in the vicinity, two of which are near the camp and supply the mill and the inhabitants with water.

The camp is about eight miles from Sodaville on the Carson & Colorado railroad. Ore from the Oneida mine is hauled by teams to Sodaville; thence shipped by rail to Kinkead, twelve miles, where it is worked. This mine is owned by Knapp & Co. and is considered very valuable. The vein is small but rich.

The outlook for a permanent and prosperous mining camp is good. The formation is soft and in many of the mines the ore is decomposed and resembles corn meal.

DELAMAR. — *Lode:* Wm. Perry has the contract from the DeLamar Company to haul the hullion from DeLamar to Milford, Utah. The contract calls for $40,000 per week, or $160,000 per month.

The DeLamar Company's tramway will be finished and in running order in a few days. The working of the tramway is very simple and is not an endless rope as at first supposed. There are two large cables—one and one-half inch—made fast at both ends, and will support 10,000 pounds each; the cables weigh 6000 pounds. The cars are suspended from the main cable and run on wheels. There are two smaller cables, one attached to each car. The cars work automatically, the loaded one taking the empty one back. The cars are self-dumpers. The distance between the mill and mine is 23,000 feet and the distance is to be made in eighteen seconds.

Wm. DeFreiz is chief caterer for the DeLamar Water Company, and the liquid fluid is one cent per gallon, or forty cents per barrel.

Lode: Work is being pushed rapidly at the De Lamar Co's mill. The Company's office is the finest building in the State. A greater portion of the machinery for the mill is now on the road and will be put in place as soon as it arrives. The mill is expected to be in full operation by the 15th of March. A force of about fifty men are working in and around the mill.

ARIZONA.

Journal-Miner: The Gladiator mill is pounding away with a full force of miners and mill men, paying handsomely.

At the Crowned King, one of the richest mines in Arizona, the mill is running steadily. Since greater depth has been reached on this property, water has been developed which guarantees a steady supply for the mill for the future.

On the Hassayampa, Mark Bradley and partners on the Oak mine are down 100 feet with a shaft in free gold ore that will run $100 to the ton. It is said that they recently milled twenty tons of ore and received $1800 by it. They have now seventy-five tons of ore on the dump and are only waiting for the completion of the new road to transport this shipment to Tomlinson's mill on the Hassayampa, six miles distant.

Thompson, Rowe & Co. are working "Old Often" mine steadily. This name will be recalled by all old timers, from the fact that hack in the early sixties it was worked by the arrastra process by Bill Kirkland and others, yielding over $71,000 in gold. The above miners are now running levels on the mine, and are said to be taking out very rich rock.

On the Jersey Lily they are down 185 feet. Two levels are being run in a very rich grade of ore and the mine continues to give an excellent account of itself. Seven tons of ore recently shipped to the Arizona Ore Works in Prescott yielded $252.70 per ton. It is said that for fifty-seven feet in the main shaft of this mine there is exposed as fine a looking body of ore as the mine ever had, and it is the intention now to give the property a thorough and systematic opening.

A shaft of the Congress mill broke last Saturday, causing the hanging-up of ten stamps. While nothing authoritative is given out from the above property, miners say, however, that it is yielding more of the yellow metal than ever before, and that the mine is hardly prospected as yet. Over 200 men are on the pay roll, while the town has at least 500 residents.

COLORADO.

ACCIDENTS IN MINES.—H. C. Acker, Colorado State Inspector of metalliferous mines, has made his official report to Governor Waite for the past two years. The report gives the following recapitulation of the condition of mining labor in that State: Number of mines working, 16,794; mines visited, 985; number of visits, 1,232; fatal accidents, 50; non-fatal accidents, 100; miles traveled, 34,287. On the subject of accidents and their prevention Mr. Acker says:

"Many accidents have been caused by attempts to drill out loaded holes which have failed to explode; deficient cages have caused others; tapping loaded holes with metal bars has contributed its quota to the death list, and it has happened that weak timbers were responsible for deaths because they were set by an incompetent man.

"Generally speaking mine owners have shown a commendable disposition to promptly comply with all reasonable regulations having in view the safety and protection of men in their employ. The law providing for the inspection of metalliferous mines has for its main object the protection of the lives of the most numerous class of our wage-workers engaged in what is perhaps the most hazardous of all occupations. Skilled miners know these dangers and generally do their best to avoid them, but incompetent men sometimes employed at lower wages not only endanger themselves, but often cause the loss of the lives and property of others.

"To obviate these direful results, and in view of the fact that druggists and plumbers are required by State law to fit themselves by study and experience to fulfill their duties with safety to their fellowmen, miners should be required to give some evidence of their qualifications before being employed. Corporate owners should also be compelled to see that foremen and those directly in charge of bodies of men engaged in so hazardous an employment as mining are competent to carefully care for the safety of the men under them."

He also recommends that no giant powder be stored within 100 feet of the mouth of the tunnel, and the adoption of an eight-hour law for miners.

IDAHO.

The Wallace *Miner* says: During the past month fully five hundred men have been thrown out of employment in the Cœur d'Alenes, and with exception of about one hundred men who last month got $2.10 and $2.50½ a day, all were receiving $3 or $3.50 per day. With the exception of about forty, practically all of these five hundred men, had they acted in accordance with their own wishes and those of their employers, would have been working to-day and most likely would have continued so all winter.

GREAT PLACER MINE SCHEME.—At a point on the south fork of the Payette, a short distance below its confluence with the Deadwood fork, the stream makes a great bend. At the point of nearest approach, where the river doubles back itself, its waters are separated by only 800 feet. Gulches lead up from either side, leaving a ridge about 200 feet wide and 200 feet high. The river flows a mile and three-quarters around the great bend beyond this point of nearest approach.

The bed of the stream is known to be rich in gold, different parties having taken out large sums by working along the edges at low water. There are hot springs all along the horseshoe from which gold can be scooped in considerable quantities.

This placer ground has been located by J. S. Batchen of Denver, president of the American Red Stone Company; A. Campbell of Chicago and Samuel Gillilan of Cedar Rapids, Iowa. They have admitted L. E. Farnham of Detroit to an interest and purpose to cut a channel for the river through the neck of the bend. This will leave the river bed dry for the entire distance of one and three-fourths miles, and it is believed the ground will yield enormously. It will be mined with water taken either from small streams that flow in or from the main river at the dam that will be built to divert the stream.

They have not decided whether they will make a tunnel or an open cut. If a tunnel be constructed it will be about twenty feet square. If a cut be decided upon it will, for a short distance, be 200 feet deep. The work will cost fully $25,000. It will be begun early in the spring.

Messrs. Farnham, Batchen and Gillilan are now in Boise, says the *Statesman*. Mr. Batchen has a bottle of gold which was taken out with a pan about ten days ago. It contains $108, and is the result of four and a half days' work, of four hours each, by two men, working during the warm part of the day.

NEW MEXICO.

At Cerillos the Santa Fe Placer Association are down twenty-two feet with the caisson in the bed of the Galisteo river, the last four feet being through loose rock. The caisson was recently wedged in the rock, stopping work for twenty-four hours; a pile driver was rigged, however, and they are now going ahead all right. Several satisfactory tests have been made.

The Van Smelting Company has been organized to work mines situated at Hanover, Pinos Altos, Pine Springs, and for smelting and reduction of ores at Silver City. The company has acquired control of several mines, and has a lease upon the Flaglor smelter and reduction works. It is capitalized at the modest valuation of $10,000.

The new smelting plant being erected by the American Lead and Zinc Smelting Company at Hanover is about finished.

UTAH.

SWANSEA MAY BE CLOSED. — *Tribune:* Messrs. Geddes, Snider, Brinker and Carpenter, directors of the Swansea mine, went down to Silver City on a tour of inspection Tuesday and, though everything was found to be highly satisfactory at the mine, it was partly decided to close down and cease all operations for the present. This move is made imperative by the exorbitant smelter charges, for, although there is a good ore body in sight, and last year's shipments ran ninety ounces of silver to the ton, the company cannot afford to ship ore at the present low price of silver and the heavy and burdensome working charges.

A PUMICE QUARRY.—Cleveland and Chicago capital to the amount of $500,000 takes control of the pumice stone quarry in Millard county, Utah.

The property is located five miles from Black Rock and consists of a mountain of pumice stone, covering an area of forty acres. The stone is of the purest character, such that it can be marketed and consumed for all purposes directly in its crude state.

Hitherto, every ounce of pumice stone used in the United States has been imported from some island to the south of Italy where the only known deposit in the world was said to exist. Because of its not being produced in America there has been no tariff upon it, but the Italian government levies a royalty of $5 per ton upon the entire output, so that it has never been cheaper in this country than two and a half cents per pound. Four firms in the United States import it, and have a monopoly upon it. They are Messrs. Wadell, Van Amridge, Hermann Barr and Davis. Not a pound of pumice used in America fails to pass through their hands.

To verify the rarity of pumice as a mineral deposit it is only necessary to cite the confusion that came over the local land office the other day when Mr. Quigley tried to file his papers. Both Mr. Harris and Colonel Anderson, the special interior agent, searched the statutes for a law to cover the entry, but failed to find it, so that Colonel Anderson exclaimed to Mr. Quigley:

"Well, you deserve a gold medal in having discovered something new that is not covered by the United States land or mineral law."

No pumice claim had ever been filed in the General Land Office.

Some idea of the possible market that will open up for the pumice can be obtained from the fact that one Cleveland (O.) firm has already agreed to take from 4,000 to 8,000 tons per year.

The analysis of the pumice shows as follows: Water, 4.47; silica, 71.79; alumina, 12.92; oxide of iron, 1.94; lime, 1.09; soda and potash, 8.32.

A SALT LAKE BONANZA.—*Tribune:* According to the statement of the owners, who are gentlemen whose truth and veracity has never been questioned, a ledge of gold that has assayed as high as $1800 per ton and never less than $30, with an average of $290, has been uncovered at the mouth of Little Cottonwood canyon, less than eighteen miles from the city limits of Salt Lake. It is owned through a Government patent, very recently issued, by a regularly incorporated company of prominent citizens who have known of its existence for two months, and who had been hunting for it for six months previous to its discovery. Yesterday a gang of five miners was sent out to begin regular development work.

OREGON.

MINING ON ELLIOTT CREEK.—G. W. Boggs, who recently bought the Elliott Creek mining property, has placed a force of men at work developing it. He will build a ditch about two miles in length, of the capacity of 2,000 gallons, with 250 feet pressure. He intends to run two or three six-inch giants. The water supply will be continuous and the work can be prosecuted without interruption. Mr. Boggs has had one six-inch giant in operation for the past six weeks, and the gravel shows up far better than was expected. Work will be pushed with the ditch, and it is expected it will be completed in sixty days. The property contains 450 acres, with an average depth of twenty-five feet, and the whole of it has been sufficiently prospected to justify putting in a large plant.

WASHINGTON.

AINSWORTH MINES.—The concentrator was started this week and about fifty men are employed on this and other construction. The company also has sixteen men working on the Bluebell. A large load of ore from this property has been shipped to the smelter. The company also has fifty men cutting wood for coke for the furnaces and fuel for the engines and electric light plant.

J. McVicar, has twenty-two men at work and shipped fifty-six tons to Pilot Bay.

The Black Diamond is increasing its force, and taking out a shipment of 500 tons, which will probably go to Great Falls in the spring. Jones & McLean are still driving ahead on their tunnel contract for the Canadian Pacific Mining & Milling company and the company itself is driving a tunnel in another part of the claim.

There has been considerable talk lately about organizing a miner's union here and in the Slocan country, but sentiment seems to be considerably divided and as yet nothing definite has been done.

Every Inventor Wants a Good Patent

Or none at all. To secure the best patents Inventors have only to address DEWEY & Co., Pioneer Patent Agents, No. 220 Market St., San Francisco.

There are many good reasons why Pacific Coast Inventors should patronize this Home Agency.

It is the ablest, largest, best, most convenient, economical and speedy for all Pacific Coast patrons.

It is the oldest on this side of the American continent, most experienced, and in every way reliable.

Conducted from 1863 by its present owners (A. T. Dewey, W. B. Ewer and Geo. H. Strong), this agency has the best knowledge of patents already issued and of the state of the arts in all lines of inventions most common on this coast.

Patents secured in the United States, Canada, Mexico, all British colonies and provinces, England and other civilized countries throughout the globe.

Caveats filed, assignments duly prepared, examinations made, and a general Patent Agency business conducted.

Established and successfully and popularly conducted for nearly thirty years, our patrons number many thousands, to whom we refer with confidence, as men of influence and reliability. Old and new inventors are cordially offered the complimentary use of our library and free advice, etc. No other agency can afford Pacific States inventors the advantages possessed by this well-established and experienced firm. SAN FRANCISCO.

Coast Industrial Notes.

—The Everett, Wash., paper mill is being put in shape for a long run.

—About $5000 worth of salmon is shipped East daily from Washington State.

—Morris Bros.' Seattle foundry, recently destroyed by fire, will be rebuilt.

—The C. P. R. cement works at Vancouver, B. C., will be ready for operation Feb. 1st

—A. H. Schierholz, head draughtsman at the Risdon Iron Works, has invented an ore crushor.

—The proposition to organize a "shingle trust" in Washington State has been temporarily abandoned.

—Jas. D. Hague is reported to have bought the franchise for the electric railway between Nevada City and Grass Valley.

—The S. F. Pine Manufacturers' Association is about dead. The Pacific Pine Lumber Co. has advanced its prices 50 cents. There is a better lumber demand and a brigbter prospect for business.

—The Pacific Coast Steamship Company announces a radical reduction in passenger rates from Seattle and Tacoma to Alaskan points. First-class faro is cut from $52 to $20, and second class $30 to $10.

—Last year the New Vancouver Coal company shipped 280,018 tons; the Wellington mines 24,949 tons, and the Union mines 203,598, making a total of 741,765. The total shipments for 1893 were 718,823 tons.

—Mexican cattle sell at $5 to $12 a head, Mexican money, or $2.50 to $6 a head, American money. All the cattle a man wants may be obtained for $3 a head, American money. Sonora cattle are on the market in abundance and are liable to stay there, says the *Border Vidette*.

—The naval appropriation bill practically contains in it $5,000,000 for California. It is expected that Secretary of the Navy Herbert will award one of the $4,000,000 battleships to the Union Iron Works, besides two of the torpedo boats. The Mare Island yard is to build one of the new torpedo boats.

—Horses are as cheap in Oregon as in this State just now. A herd of 800 head, just off the range, was sold at an average price of $5 each, recently, and a few days ago, at a sale of fine stock near Portland, a splendid matched team of sorrel mares were sold for $40 and a big bay horse brought only $22.50. Half a dozen years ago such horses would have sold readily for $100 to $150 each.

—The receipts of treasure per Wells, Fargo & Co's express during the twelve months ending December 31, 1894, were $11,586,717, as follows: From the interior, $10,813,357; from the north coast, $773,360. This treasure consisted of $6,527,129 in coin, $3,005,313 in silver bullion, and $2,050,275 in gold bullion. The inland shipments from San Francisco during the year were $26,743,102, and the overland shipment $8,668,980.

—The big American ship Kenilworth from Honolulu takes the first cargo of Hawaiian sugar ever sent direct from the islands to New York. She can carry 3200 tons of sugar. The California Sugar Company conducts this new enterprise. It has arranged to ship two-thirds of the Hawaiian sugar to San Francisco, where it will be refined, and the remaining third to New York. As one-third of the Hawaiian crop is estimated at 30,000 tons, this will load ten of the largest American clipper ships.

—F. M. Hatch, Hawaiian minister of foreign affairs, who came up on the last steamer, says that the main object of his trip is to push the project for a cable between this city and Honolulu. He says the Hawaiians do not like the idea of foreign capital invested in an enterprise which they think should be purely American. Hatch says if capital cannot be secured in this country it will be sought elsewhere. The plan of the Hawaiians is to utilize Neckar island as a station when the cable is laid, with a supplementary line from Neckar to Honolulu.

—The Seattle Consolidated Street Railway Company, the successor of the Seattle Electric Railway and Power Company, operating the Second street line and its branches in Seattle, Wash., has been sued in the United States Circuit Court under foreclosure proceedings brought by the Illinois Trust and Savings Bank of Chicago, trustee, on a mortgage for $400,000, covering an issue of bonds, March 15, 1890. Default in the payment of coupons under the trust deed was made April 1, 1894, and the bank now asks that the mortgaged property, covering all the holdings of the company, be sold as an entirety and without the right of redemption, to satisfy the sum due upon the bonds.

—The Pierce County, Wash., Power and Telegraph Company have applied for permission to build and operate an electric power plant in Tacoma for manufacturing, railway and other purposes. They propose to put a dam across the Nisqually in order to get a fall of water to run the dynamos, and will put in a large amount of expensive machinery. A new company has been formed in Tacoma growing out of the purchase and combination of the Tacoma Light and Water Company with the Commercial Electric Light and Power Company. The reputed purchasers are Seymour, Barto & Co., C. B. Hurloy, and some Eastern men who make a specialty of the gas business. Mr. Hurley has become manager of the consolidated plants.

FOR SALE.

1 Latest Improved Bruckner Furnace.
2 Chlorinating Cylinders of cast iron, lead lined.
1 set Krom Rolls.

The above in use but a short time. For sale cheap. Address L. C. S., Box A., Mining and Scientific Press Office, S. F.

In Our Lap=

WELDED PIPE (MATHESON JOINT, for which we are agents) we are supplying an article of known excellence. A large line always in stock. We also make all kinds and sizes of SHEET IRON and SHEET STEEL riveted WATER PIPE for hydraulic mining, irrigation and other purposes. We want business—at least the way we make our pipe, the way we sell it and the way we treat customers would make you think so. Quotations and information furnished promptly.

RISDON IRON WORKS, S. E. HOWARD AND BEALE STS., SAN FRANCISCO

Attention Miners!

W. W. MONTAGUE & CO.

—ARE MANUFACTURERS OF—

Riveted Iron and Steel

Water Pipe

For Hydraulic Mining, Mills and Power Plants.

IRON, CUT, PUNCHED AND FORMED, AND TOOLS SUPPLIED FOR MAKING PIPE ON THE GROUND WHERE REQUIRED.

309 to 317 Market Street, San Francisco.

Mining Pipe!

STEEL OR IRON.—We make pipe of either, but recommend STEEL, it being superior to iron in many particulars and inferior in none.
COATING.—We use great care in COATING our pipe with a HOT solution of Double Refined Aspbaltum and Maltha.
COMPETITORS.—Our competitors say we have the best appointed Pipe Shop on the Coast.

SCHAW, INGRAM, BATCHER & CO., Hardware Merchants, SACRAMENTO, CAL.

WATER WHEEL

CASCADE WATER WHEEL

Adapted to all heads, from 30 FEET TO 2000 FEET. Our experience of 33 YEARS in the water wheel business enables us to suit every requirement of water power plants. Send for illustrated pamphlet. This new wheel has given an unequaled Economy in Water.

Electrical Progress.

Revolutionizing Telegraphy.

The latest announced improvement in electric transmissiou of words is of a device which it is asserted is being uow perfected for sending messages and having them written out automatically in Roman characters as rapidly as ten operators can work under the preseut system.

The phonoscope lets the speaker at one end of the telephoue line see the person addressed at the other eud. The tautograph completes this phase of invention by transmitting a photograph over a telegraph wire and recording it as received, iu the shape of a finished engraving ready for the printing press. Akin to this is the telautograph, which records an autographic message and carries it in the handwriting of the sender; but the telegraph, first in point of time, and in a sense basal, still uses arbitrary signs or signals, which are interpreted by the receiving operator into a legible message.

Every betterment successfully attempted has been in the direction of increased speed, which has brought out the various duplex, quadruplex and multiplex systems whereby several messages cau be sent over the same wire at one time. A number of printing telegraph ideas have beeu advanced, but the speed has not kept pace with the complicatiou of the mechanism.

A description received of the uew system says:

"I wrote some sentences and handed them to the operator, who sat down before an ordinary typewriter and placed therein a piece of paper, upon which she clicked out my message. At the same time it was recorded on a ribbon of paper, through a series of holes, varying in number aud location according to the characters to be represented. Next the operator placed the ribbon above a small metal roller; above this ribbon was a series of small metallic fingers, which pressed upon it. As the different holes in the ribbon came under the fingers, electrical connection was made with the roller and a duplicate was made for preservation. The ribbon remained in place while the roller made one revolution, the metallic fingers working meanwhile as if ou a typewriter.

"Only one finger at a time was connected with the telegraph wire, but in course of each revolution every finger had a chance to send out an impulse over the wire, the holes and the fingers or keys beiug adjusted to each other throughout.

"The machine upon which the message was to be reeeived was like the one upon which it was sent. It comprised a disk with the same number of divisions iu its rim and a brush sliding against it. Iu this case each of these divisions was connected with a separate magnet, eight of them being placed in a circle, each magnet having an arm pointing toward the center of the circle, so that all of the eight arms ended within the space of a Roman letter.

"One arm made the stem to a T, or the same arm made an I, if its magnet was called upon to act. If the letter was an I, only one hole was punched in the ribbon; but if it was a T there were three holes—one for the stem, another for the left-hand portion of the crossbar and a third for the right-hand portion of the bar. In this case three of the magnets moved their small arms, which made the marks described. Above the inner ends of these levers was an inking ribbon, above which was a piece of paper, of the ordiuary letter size, and held in position in the usual typewriter fashion. The movement of the magnet arms were so fast that they made their prescribed marks upon the paper before it had time to move out of place.

"It was absolutely necessary to keep the two brushes—one at the sending end and one at the receiving end—on the same part of the disks at the same time, so that each finger might be connected with its own magnet. Yet I saw my message priuted out before my eyes, line by line, properly spaced, entirely legible and ready for delivery, although the brushes were rotating 1000 times per minute. The device by which this certainty of action is achieved is, after all, simple. Each brush arm is fastened to a shaft, which also has a disk about two feet in diameter mounted upou it. On the receiving machine at one point this disk or flywheel has two metal points near each other, but insulated, and the secondary or an induction coil includes these points. The primary of this circuit at the sending end is broken once for each revolution of a similar flywheel aud brush arm at that end, and when so broken it causes a spark to appear between the points of the receiving wheel. Now, so long as the spark seems to stand still, the two brush arms and wheels are moving at the same speed. The operator corrects any irregularity by setting his thumb against the rim of the wheel.

"My message was handed to me printed out in Roman characters, and from personal observatiou I am certain that at least 200 words per minute can be received by this system. The brush arms made 1000 revolutions per minute, and one complete letter was made for each revolution.

"Ordinary press dispatches average say five letters per word. At another time the machines were speeded up to 1500 revolutions, which gave a capacity of 300 words per minute, and all this was attained without expert skill in manipulation."

By this system the business man could dictate a message to his stenographer, who, in writing it out on the typewriter, would at the same time produce the perforated ribbon, so that the ribbon itself would be presented at the telegraph office and the message automatically forwarded.

With the best type printing telegraph systems now in use or proposed, the speed is limited to the speed of the operator, because a key is operated for each letter to be recorded, while in this system the sending speed is regulated by the number of rotations of the transmitter. If 2000 revolutions were maintained, then 2000 letters or characters would be transmitted per minute, all received on a printed page, ready for delivery.

The people who are getting ready to put this invention into use are confidently putting up their first line between Washington and Baltimore, over the same route that was traveled by Prof. Morse's trial line in 1844.

Big Electric Locomotive.

Although the electric locomotive of the Baltimore and Ohio road is to be used only for hauling trains through the Mouumental City, and not for express service, the experiment of building and using it is watched with great interest in railway circles. It is to be composed of two four-wheel trucks, and has a 300-horse power motor on each axle; and when completed it is expected to weigh ninety-five tous. While capable of making a speed of fifty miles an hour when ruuning light, it will probably run at only thirty miles with half a load, and fifteen with a full load. It is designed, however, to handle quite as heavy traius as the best steam locomotives.

One truck, which is finished, was recently tested at Schenectady. Being connected with a good-sized New York Central engine, the two were set to work, pulling against each other. The electric truck, although only half as powerful as the machine of which it is to form a part, weighed slightly more than its competitor, and therefore had a little better grip on the track. It pulled the steam locomotive up and down the road with apparent ease. This fact, among others, was clearly demonstrated: Weighted equally with a steam locomotive, the electric motor will start a heavier load from a stationary position. The pull is constant during the whole revolution of a drivingwheel in the one case, while in the other the angle which the crank makes with the line of draft causes a variation in the effective power.

The whistle of the new engine will be operated by compressed air, afforded by au air pump which also serves the air brakes. There will be a Janney coupler at each end. The current is to be supplied from a power station, and taken into the motor by an overhead trolley. The generating apparatus will be installed and the line in working order before many weeks.

New Telephone Signal.

On the first of next month the Chicago Telephone Exchange will operate a new system of signals by which a great saving of time will be effected. The subscriber will then simply take down his receiver, and instantly a little electric light with his number will flash in front of the operator. As the subscriber takes his receiver he calls the number he wishes, and the connection is made at once. At the end of the conversation the hanging up of the receiver lights another lamp which directs the operator to disconnect.

The new system is the outcome of experiments which have been goiug on for a year in this city aud Chicago. Three hundred and forty thousand persous use the telephone in Chicago. The number of calls in the twenty-four hours of each day is 115,000. Under the present system the number of calls that could be answered in an hour was 200. Under the electric signal system the number of calls that can be answered will be 600.

Continuous copper wires of the Postal Telegraph Cable Co. now admit of direct, simultaneous connection between this city and New York or Chicago, it being now possible to send a message from here to either of those cities and receive an answer in two or three minutes.

The much-talked-of electric railway from Merced to the Yosemite is assuming tangible shape, and it is manifest that the four-days round trip will be made a thing of the past. The plan involves the expenditure of a very large amount of money—nearly $2,000,000.

Electricity, of New York, is doing good work in exposing some of the frauds that have fastened on the electric business as they will fasten on any line of commercial pursuit. Just now the Electropoise and the Electrolibration Co. are receiving needed exposure.

The Western Electric Co. proposes to make matters lively for some of the new telephone companies, and has begun suit against them for alleged infringement of some of its numerous patents.

It is not so very long as time goes since incandescent lamps were $1.00 each. In '91 they were 50 cents. Competition and a free field have brought the price now down to 21 cents.

The Edison Light and Power Co. is about ready to begin its proposed outlay of a quarter of a million dollars in changing its overhead wires to the uuderground system.

An electrical horse power is the electrical power of an electrical current the product of whose volts and amperes is 746.

20-Stamp Mill for Sale.

In Southern California, a 20-stamp Gold Quartz Mill, with engine, boiler, self-feeders, rock-breaker, etc.

As the premises are adjacent to Railroad, the Mill could be conveniently removed. Can be had at low price for cash. Address: "Quartz Mill," care MINING AND SCIENTIFIC PRESS, San Francisco.

Wire Rope Versus Electricity.

Henry Rowan doesn't agree with J. T. Fargie on the latter's paper, recently read before the Scottish Mining Institute, in which electric transmission of power for mining purposes was advocated.

According to Mr. Rowan the first cost and necessity for high-priced attendance with electric power far outbalances the asserted economy of operation, and places wire rope transmission in the lead.

According to his figures the cost of transmission from the surface to the haulage plant in the mine below was, for a particular case, very closely as follows:

FIRST COST

Rope transmission	$1,057 50
Electric transmission	5,427 50
Difference in favor of rope plant	$1,370 00

YEARLY EXPENSES.

ELECTRIC PLANT.

Interest, etc., on $5,427.50 @ 10%	$542 75
Engineer, 280 days	326 50
Motormen, 560 days	606 50
Total per annum	$1,475 75

WIRE ROPE PLANT.

Interest, etc., on $1,057.50 @ 10%	$105 75
Depreciation of ropes at 50%	228 75
Attendance, 280 days	233 33
Additional labor	82 25
Total per annum	$650 08
Difference in yearly expenses in favor of wire rope	$825 67

Black Hills Gold and Silver Product.

The amount of gold produced in the Black Hills during the year 1893 was 221,675,858 ozs., and the coinage value $4,119,083.27; silver, 137,915.20 ozs., of a coinage value of $96,540.64. Conservative and well-informed mining men, says the *Pioneer*, place the product of 1894 at: Gold, 443,351,716 ozs., coinage value $8,238,166.54; silver, 172,394 ozs., value $120,675.80.

The gold product of '93 was distributed as follows:

Homestake, Highland, Caledonia, Deadwood, Golden Reward	$3,318,237 58
Columbus	49,000 00
Colcita G. & S. Co	4,000 00
Mark Twain	3,080 00

Burton	2,347 80
R. B. Hayes	1,453 99
D. & D. Smelter	72,000 00
Total	$96,540 64

He Knew Too Much.

The death of the late Jas. G. Fair brings to the surface a good many anecdotes of "Uncle Jimmy." The following is believed to be new:

A body of rich ore was struck in a drift, and speculative reasons made it necessary to hide the news from the public for a few days. The Senator, in his flannel shirt and oilskin hat, sat down with the resting miners in the drift; and, picking a piece of rock from a passing car, remarked:

"That's pretty good stuff; don't you think so, boys?"

There was a murmur of respectful assent from a few.

"What do you think of it, Johnson?"

Miner Johnson, who was aequainted with Fair's ways, examined the rock critically, shook his head, and said it looked barren to him. Several others did the same. Miner Murphy, a comparative tenderfoot, saw an opportunity to distinguish himself. "That rock, sir, will go all the way from $150 to $300 a ton."

"Ah," murmured the Senator, admiringly, "you're a miner, Murphy. You understand your business." Then to the superintendent in the office presently: "Brown, discharge Murphy from that drift. He knows too much."

THE ten deepest mines in Silver Bow county, Montana, are the Alice, which is down 1500 feet; the Lexington, 1500; Gagnon, 1250; East Gray Rock, 1300; High Ore, 1200; Anaconda, 1200; St. Lawrence, 1100; Mountain View, 1100; Silver Bow No. 1, 1100; and the Green Mountain, 1000.

No. 10.

ALASKA TREADWELL GOLD MINING COMPANY
Alaska Mexican Gold M'g. Co.

Douglas Island, Alaska, July 31st. 189.

William J. Chalmers Esqr.
Pres. Fraser & Chalmers.
Chicago. Ill.

Dear Sir:-

Your letter of July 7th. is duly received.

In regard to your enquiry regarding our Riedler Compressor, supplied by your Coy, over eight months ago, I must say, that the Compressor is giving excellent results, and every satisfaction, while running either by steam, or water power.

During the last twelve years, I have seen operated, and have operated, many different makes of air Compressors, including the Eclipse, Reliance, Burleigh, National, Rix, & Firth, Ingersoll Sargent, etc. etc. and in no instance, have any of the above given the results of the Riedler. Therefore, I have no hesitation in saying that the Riedler, is the best, and most economical Compressor on the market today. We have made comparitive tests here, of the Ingersol Sargent, and Riedler, which show, greatly in favour of the Riedler.

Yours very truly,

Robt. Duncan Jr.
Supt.

A Word of Caution.

The necessity of keeping close watch over mining claims and of taking all the required legal steps to perfect title has been shown in the Coulterville district lately. In one instance a mine (patented, we believe), upon which a mill was in operation, was jumped, and several instances are reported where claims have been "appropriated." There are men who will resort to almost any means to secure desirable claims; and even though their efforts do not win, the owners are put to considerable expense. A claim is never safe until it is patented; and if a claim is worth holding, it is certainly worth patenting. It is a matter of negleet with most men that they have not secured patents, but it is liable to prove a dangerous oversight. Now that so many new men are in the county, the likelihood of trouble from this source is increased. It will prove the part of wisdom for every man who has a good mine to seeure a patent as soon as possible.—Mariposa Gazette.

THE State Gas Inspector of Indiana reports that the natural gas supply of that State will be exhausted in less than four years. He further estimates that at least $25,000,000 worth of gas has been wasted in Indiana.

THE weight of fir spars per square foot is three and one-third pounds.

Mining Share Market.

SAN FRANCISCO, Jan. 24, 1895.

During the week, for the first time in many moons, there was a coincidence between encouraging mine reports and a strong market. An advance is noted in the leading North End stocks. The superintendents' reports, almost without exception, show improvement. In the Con. Cal. & Va. work has been resumed in the newly discovered ore which is making into the old ground. Ophir is also reported looking favorable. Last week's efforts of the shorts to depress prices were counteracted.

In the market, as in all other similar enterprises, the smaller the purse the less the chance of success. There is hut little use in sitting into the game on table stakes. The man with the shallow purse is no match on the street for the capitalist. Where there is a contest weight tells, and there is always a contest in the stock market.

The Bangkok-Cora-Bell Mining Company of Colorado paid a dividend of one cent per share, amounting to $6000, January 15th. The Forepaugh Mining Company of Colorado paid a dividend of ten cents per share, amounting to $16,000, January 10th. The Mollie Gibson Consolidated Mining Company of Colorado has declared a dividend of five cents per share, amounting to $50,000, payable January 25th.

Bullion valued at $29,200 has been sent to the Carson mint from the Con. Cal. & Va., being the final shipment for December, during which time there was produced bullion valued at $90,990.40.

The bullion statement of the Con. Cal. & Va. for December is as follows: Worked at the Morgan mill, 2124 tons. Bullion produced—Silver, $48,785.86; gold, $42,204.54; total, $90,990.40. Yield in hulliou per ton—Gold, $19.86; silver, $22.96; total, $42.82. Assay value of the ore per ton per battery samples—Gold, $20.04; silver, $30.07; total, $50.12. Assay value of the above ore per ton per railroad car samples, $50.71.

Less than 1000 shares of the Hale & Norcross were delinquent.

The following illustrates the changes of the week:

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING JANUARY 15, 1895.

532,742.—SEPARATOR—H. Arden, Seattle, Wash.
532,628.—HAIR DIPPER—C. W. Babcock, Portland, Or.
532,527.—PUMP—J. P. Cahill, Oakland, Cal.
532,663.—BAND SAW MILL—D. B. Hanson, S. F.
532,461.—SURGICAL SPLINT—R. Hoppe, S. F.
532,703.—LOCK—W. G. Rex, Shelton, Wash.
532,585.—CURRENT WHEEL—Seivert & Young, Medical Lake, Wash.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Assessment Notice.

DUMBARTON LAND AND IMPROVEMENT COMPANY.—Location of principal place of business, San Francisco, California. Location of works, in the counties of Alameda and Santa Clara, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 22d day of January, 1895, an assessment (No. 7) of 12¼ cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, No. 214 Pine street, room 55, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 28th day of February, 1895, will be delinquent, and advertised for sale at puolic auction, and unless payment is made before, will be sold on THURSDAY, the 21st day of March, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

JABEZ HOWES, Secretary.

Office, Room 55, 214 Pine Street, San Francisco, California.

Roasting of Gold and Silver Ores.

BY GUIDO KUSTEL, M. E.

This rare book on the treatment of gold and silver ore without quicksilver is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, $3, postpaid. For sale by THE DEWEY PUBLISHING CO., 220 Market St., San Francisc.

MINING SHAREHOLDERS' DIRECTORY.

Assessment Notices.

GOULD & CURRY SILVER MINING COMPANY—Location of principal place of business, San Francisco, Cal.; location of works, Virginia, Storey county, Nev.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 17th day of January, 1895, an assessment (No. 75) of fifteen cents (15c) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, room 69, Nevada block, 309 Montgomery street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 19th day of February, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on TUESDAY, the 12th day of March, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

ALFRED K. DURBROW, Secretary.

Office—Room 69, Nevada block, 309 Montgomery street, San Francisco, Cal.

REED MILL AND MINING COMPANY—Location of principal place of business, San Francisco, California. Location of works, Ferguson Mining District, Helene, Lincoln County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 31st day of December, 1894, an assessment (No. 1) of two (2) cents per share, was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, room 33, tenth floor, Mills Building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 28th day of February, 1895, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on WEDNESDAY, the 3d day of April, 1895, to pay the delinquent assessment, together with the cost of advertising and expenses of sale.

By order of the Board of Directors.

JOHN H. ISHAM, Secretary.

Office, Room 33, tenth floor, Mills Building, San Francisco, California.

BULLION MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Virginia district, Storey county, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 21st day of January, 1895, an assessment, (No. 44) of 10 cents per share was sold on THURSDAY, the 21st day of March, 1895, levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the company, Room 21, No. 331 Pine Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 26th day of February, 1895, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

R. R. GRAYSON, Secretary.

Office, Room 21, No. 331 Pine Street, San Francisco, California.

CRESCENT MINING COMPANY—Location of principal place of business, San Francisco, California; location of works, Mokelumne Hill, Calaveras County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 15th Day of January, 1895, an assessment (No. 1) of 10 cents (10c) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of he company at Room No. 69 Nevada Block, No. 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 16th day of February, 1895, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 11th day of March, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

ALFRED K. DURBROW, Secretary.

Office—Room No. 69, Nevada Block, No. 309 Montgomery street, San Francisco, California.

INYO MARBLE COMPANY OF CALIFORNIA.—Location of principal place of business, San Francisco, California; location of works, Inyo, Inyo County, California.

Notice is hereby given, that at a meeting of the Board of Directors held on the 21st day of January, 1895, an assessment (No. 26) of ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, Room No. 13, third floor, Mills Building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 6th day of March, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on FRIDAY, the 5th day of April, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

W. W. SARGEANT, Secretary.

Office—Room 13, third floor, Mills Building, San Francisco, California.

RUPTURE!

IT has been considered by the medical profession that hernia—commonly called rupture—was incurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But DR. J. C. ANTHONY, of 86 and 87 CHRONICLE BUILDING, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patient no pain, and those living near enough do not lose any time only while in his office once or twice weekly. He guarantees every case he treats, and does not ask a man for a dollar unless he cures him, so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medical College, of New York City.

Mining Property For Sale.

The valuable gold mining property belonging to J. F. GREGG, in the

Plymouth Mining District, in Amador County,

On the "Mother Lode," will be sold at SHERIFF'S SALE to the highest bidder to satisfy a mortgage. Sold at

PUBLIC AUCTION!

On COURT HOUSE STEPS in

Sacramento City

—ON—

February 2d, 1895.

This property contains two hundred acres of land and two large, well defined, gold bearing quartz ledges run the entire length of the property, one mile in length. There is no question about the Mother Lode running through this property. In fact, the Mother Lode at this point is very wide and this property is all "Mother Lode."

It adjoins the famous "Plymouth Consolidated Mines," operated so many years by Hayward, Hobart & Co., from which mines they took many millions of gold.

Mr. Gregg is the original owner of this property, having lived on it for upwards of forty years. He has been holding against all propositions of buyers, hoping to keep it until he could get a good price, but the financial reverses of the past two years have forced him to the wall, and the property will now be sold, in all probability, for less than its agricultural value, which he has always placed at $10,000.

Any persons who may desire to learn anything further in regard to this property would do well to address M. L. GREGG, 1203 Broadway, Oakland, C. A. HITCHCOCK, 549 Albion St., Oakland, J. H. ROUSE, 420 Ninth St., Oakland, or E. C. SUINAN, East Oakland.

Colorado Mining Stock Matters.

The mining stock transactions, both local and otherwise, chronicled during the past week have not had any tendency to improve the situation, but to the contrary matters have been seriously injured. A few more unfortunate manipulations like the one recently experienced in Mollie Gibson will soon dispel what little desire remains on the part of the public to purchase mining stocks.

The disgraceful proceedings practiced by the Pharmacist Co., of which all are unfortuuately too familiar, does not increase confidence, and has the effect of disgusting every one interested in mining stock speculation.

If matters continue to go on in what are generally considered corrupt channels, mining and everything connected with it will be looked upon with the utmost suspicion, and Exchauges will be considered licensed institutions for the protection of such questionable operations. Surely mining is already looked upon with enough suspicion without the dealings like the present being further countenanced.

I am daily in receipt of communications of condemnation throughout the East, and am assured that other brokers are being also flooded with letters of this class. Many avow they will never consider another Colorado mining investment; stated their experience in listed stocks is more disastrous than that of the unlisted, and it is utterly impossible to obtain any reliable information, which is undoubtedly true, as those interested pay more attention to manipulating or otherwise sealping the market than to furnishing customers with appreciable faets.

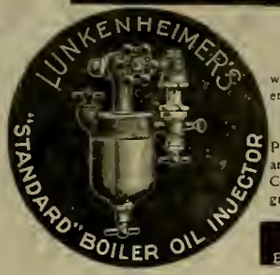
The Mollie Gibson is considered geuerally responsible for the bitter feeling now existing. Many in a position to know assert that the high-grade ore is exhausted. It is also claimed that many of the heavy holders took advantage of their prior knowledge of this faet and disposed of their holdings, thoroughly ignoring any moral obligation one is supposed to assume in prominently associating themselves with a corporation.

I do not antieipate any renewal of activity until people are placed in a position where they can understand matters more to their satisfaction and on a business basis.

This reckless buying and selling on the part of those who should endeavor to ereate confidenee, regardless of values, must cease. The market is purely professional, and has been for many weeks, and will continue to be indefinitely unless a reform of the present methods is brought about. Even dividend payers are not in good standing and are looked upon with distrust. This is not strange, considering the present outlook. The only redeeming point is that most of the properties represented by the gold stoeks are improving and intrinsieally more valuable than at any time in their history. Very respectfully, F. H. PETTINGELL.

Colorado Springs, Col., Jan. 19, '95.

BOILER OIL INJECTORS



Progression is the order of the day.

Attach one of "LUNKENHEIMER'S" to your boiler and you will be astonished with results. The **only injector** made that will entirely free your boiler of scales

Practical in Construction; Simple in Operation.

Provided with a visible feed. Sizes ¼ pint to 1 gallon. Specify and insist on "LUNKENHEIMER'S" and you will get the best. Consult Dealer. New Catalogue of Superior Steam Specialties, gratis upon request.

Ore Deposits of the United States.

By J. F. KEMP, A. B., E. M., Professor of Geology School of Mines, Columbia College.

Second Edition, Revised and Enlarged, New Illustrations.

A practical review of the ore deposits of this country. A valuable addition to up-to-date mining literature, of value to the Pacific coast. Sent postpaid upon receipt of price, $4.00. Address

Mining and Scientific Press,

220 Market Street, San Francisco, Cal.

The Explorers' and Assayers' Companion.

A Third Edition of Selected Portions of the "Explorers', Miners' and Metallurgists' Companion."

By J. S. PHILLIPS, M. E.

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying and Metallurgy.

The work is divided into four parts: Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay has been kept as free from formulæ as possible. The work is written for practical men, and all the explanations and discriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

Price $6.00 postpaid. Sold by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco

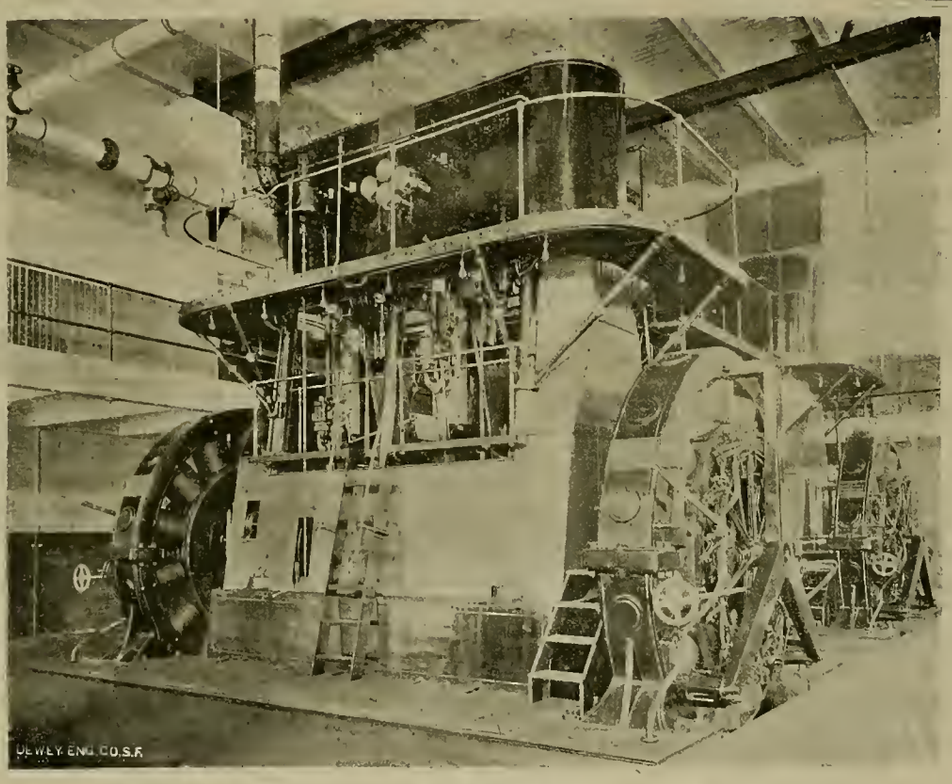
Lick Observatory Jan 1895

Edison Light and Power Co.

The accompanying illustration is of one of four similar mammoth electric generators in use in the station of the Edison Light and Power Co. on Stevenson street, this city. It is from a photograph taken by Mr. F. E. Smith, the company's chief electrician, an amateur photograper of no ordinary ability, whose daily duty and delight it is to oversee the workings of the company's huge plant.

The company is now engaged in changing its system from overhead to uuderground distribution, experience and observation showing that the latter possesses points of superiority justifying its adoption.

The principal advantages claimed for the underground as against the overhead distribution of current for light, heat and power are as follows: As all conductors are beneath the surface they cannot be interfered with by other wires, neither do they become disabled from the action of storms or burning buildings. Unlike the overhead system in which each dynamo operates its own iudividual circuit, thereby making the service dependent upon a single machine, the underground system has only one circuit, which is supplied by as many machines as the service demands, when in the event of one unit becoming disabled it is thrown out and the remaining ones carry on the work nninterruptedly. In the overhead system, when a machine becomes disabled it becomes necessary to momentarily interrupt the service while the transfer is being made.



ELECTRIC GENERATOR OF THE EDISON LIGHT AND POWER COMPANY.

All mains are connected together at street crossiugs, thereby forming a network similar to that formed by a coarse mesh wire screen, and this network supplied by feeders which furnish current to the intersections of the mains, permits of an electrical supply which would be difficult to interrupt, for the reason that if an accident should occur at one point, it would simply prevent current from flowing in at the disabled point but would not interrupt the service, as the current would still be supplied from the remaining feeding points. With the overhead system an interruption at any point on a circuit causes an interruption over the entire circuit.

The company has a splendid equipment, and is a prominent factor in the electrical progress of the city.

When a great mine has passed its usefulness as a stock scheme, it is given over to the "leasers." These men usually enrich themselves by working ground in which the great corporation could find no paying ore. The professional "leaser" is always eager to get possession of "exhausted" mines. He is the gleaner of the field after the harvesters have removed the crop, and it is often an easy matter for him to clean up a reasonable fortune from abandoned drifts and stopes.

In these days of gold finds it is worthy of note that thirty years ago some thought that the area on this coast suitable for prospecting was exhausted. Twenty years ago men said that the prospecting area was so circumscribed that in a few years there would be no new developments. Ten years ago many regions were declared "no good" that now show flattering prospects. While cheaper and improved appliances have much to do with the increased output of '94, it is manifest that suitable prospecting ground has not been exhausted and that new finds will be as plentiful in the sunrise of the twentieth as they are in the twilight of the nineteenth century.

Senator Stewart, of Nevada, may be a "friend of the people," but he effectually succeeds in disguising his feelings by promptly and continually opposing everything calculated to aid their interests. Even when the vote on the Nicaragua bill was taken last Saturday the Nevada Senator refused to vote for the measure.

Mrs. A. R. Garrison is one of the few women in California who follow the profession of mining. She has discovered some new prospects in the Panamint Range, fifty miles from Red Rock, and says she will build a ten-stamp mill as soon as the weather permits at Rasper Canyon, the name of the new mining camp.

What Recognized as Minerals.

An account appeared in last week's Press of the location of a pumice mine in Utah, and the fact was noted that the local land office officials could find no law to cover the entry when the locator tried to file his papers. The circumstance has given rise to a discussion as to what are minerals: what do the mining laws recognize as such?

In its most comprehensive sense the term "mineral" includes all inorganic substances having a definite chemical composition: so applied, all of the public lands of the United States would come under the mining act as vide the wording of Sec. 2318, Revised Statutes of the United States. But the evident meaning of the act is of course to include only such lands as contain deposits of metals and other substances giving the land a special value. Discussion occasioned the government interpretation of that matter as follows: "That whatever is recognized as a mineral by the standard authorities on the subject, where the same is found in quality and quantity to render the land sought to be patented to be more valuable on this account than for purposes of agriculture, shall be treated as coming within the purview of the Mining Act of May 10, 1872."

It goes without saying that the well known metals are included; diamond-producing land may be patented under the mining laws; borax, nitrate of soda, carbonate of soda, sulphur, alum and asphalt, also. The General Land Office has decided in entering a borax claim the proceedings shall be as in the case of placer claims. As cinnabar and copper are found in "rock in place," lands containing them must patented as lode claims. Gypsum is not a mineral be within the meaning of the Mining Act. Iron lands may be patented under that act; so, also, kaolin (porcelain clay). Limestone, marble deposits are not considered mineral lands, and such lands can be bought only under the timber and stone act of June 3, 1878. Mica, petroleum, slate and sulphur are locatable under the mining laws; likewise paint stone, oil and fire clay. Saline lands are sold under a special act of Congress of January 12, 1877, which does not apply to California. The General Land Office has decided salt as a mineral, and lands containing salt deposits have been excepted from railroad grants in Nevada. Asbestos, plumbago, manganese, etc., are held to be within the meaning of the Mining Act.

Practical mining superintendents say that in every-day use one ton of coal is equal to about one and three-fourths cords of wood.

THE highest and lowest land in the United States—Mt. Whitney and Death Valley—are within fifty miles of each other in San Bernardino Co., Cal.

FROM every part of the coast comes news of unprecedented snow and rainfall. While this works present discomfort and in some cases considerable loss, it insures abundant water supply for next season's mining operations.

SEVERAL other commonwealths are competing with California for the prestige of being the greatest gold-producing area. Meanwhile California's Legislature has before it a proposition to throttle the only one public institution representative of California's mines—the State Mining Bureau.

ELSEWHERE Mr. M. B. Kerr has some remarks on the U. S. Geological Survey and its self-constituted censors, who appear actuated by hostility more than justice. The whole matter indicates that the assumption of impartial criticism on the part of the Survey's enemies (through business reasons) but thinly veils the motives of the attack, and that it is less a desire for the public good than an effort to dragoon the department into a cessation of lines of work that brings that part of the public service in collision with private commercial interests. This is well understood, and discounts the force of the interested attack on that department.

THE proposition that a perverted idea of "economy" has introduced into the Legislature to close up the State Mining Bureau, is an utterly defenseless proposition. There is no "economy" about it. It looks more like a deplorable piece of petty, sectional spite work than any public measure that can be dignified by the title of State legislation. To do away with the museum's present location; to transfer it elsewhere, unless such transfer made it even more centrally located than it is now, would be to destroy its usefulness. Its good is in direct proportion to its ease of access. To turn the operations of the Bureau—its great and growing, inside and outside work—over to any other institution as an appendage, would be fatal to the Bureau's usefulness and would not save the State a dollar; rather increasing the expense while destroying its value. The Bureau is now finely officered, thoroughly organized and doing daily necessary work that otherwise must go undone, to the State's detriment. Transplanting it into different soil would be to defer if not wholly destroy any promise of further vitality. A homely adage says: "Let well enough alone." It is a good one to observe in this instance.

WASHINGTON is trying to create a State Mining Bureau. Idaho, Colorado, Montana and British Columbia are making similar effort. Those commonwealths realize what grand aid a properly conducted mining bureau can be in the development of the mining industry. This is an age of emulation, of competition, and the rule holds good in the exhibition of a State's mineral resources as in other developments of natural wealth. California has an efficient State Mining Bureau, which has done and is doing good work in the development and proper representation of that great industry. A few narrow-minded men who are at present in the Legislature at Sacramento have conceived the idea that it would be "economy" to do away with the Cal. State Mining Bureau, and virtually leave the State without such a necessary institution, and just at the time when our sister commonwealths, with clever understanding of the situation and its requirements, are severally creating State mining bureaus. The situation does not appear to require extended comment. The facts are plain to any one who cares to recognize them. It is folly to seriously entertain such a proposition as that introduced by State Senator Langford of San Joaquin. No severer injury to the State could be devised than the passage of such a bill, and we have sufficient faith in the common sense of the Legislature and its devotion to the interests of the great State its members represent, to believe that such an unwise measure will prevail.

PURELY as a matter of "economy"; in the high interests of "retrenchment" and "reform," it is proposed by legislative enactment to turn everything in connection with the State Mining Bureau over to the University of California. It is not denied (for it cannot be) that the Bureau is well managed; that it is a necessary institution of great public benefit; that there is no complaint from any part of the State, it being universally recognized that the Bureau is under intelligent and energetic direction. The matter is solely one of "economy." There is no spite work nor effort to injure the mining industry. It is just "economy," pure and undefiled. The State University, to which zealous legislative economists wish to give the Bureau, has a College of Agriculture, which, like any other public institution, is supported by public taxation. There are four professors, two "instructors," six "foremen," and so on. The salary list alone aggregates $22,760 per annum. The "experiment" department cost, last year, $14,579 more; that is an annual cost of over $37,000 in that one department of University work. This agricultural college has been in operation since 1873. In those twenty-two years it has graduated twenty-four students; of these twenty-four eight are engaged in agricultural pursuits. It may seem a little extravagant to spend over $37,000 a year public money in gradnating one-third of one college farmer every year and conducting experiment stations; indeed, people, miners for instance, who don't understand that kind of "economy," might think that this was a very extravagant way of manufacturing college farmers, and might also think that the interests of "economy" will not be subserved by turning over the mining interests of the greatest mining State in the Union to the University, where it costs $37,000 per annum to run the Agricultural College and the experiment stations, etc. True, miners and others can point to the great work being done by the Bureau; to its active intelligence in mining affairs; to the thousands of up-to-date publications it issues; the thousands of inquiries answered; the hundreds of thousands of dollars annually attracted to California for investment, and ask if it is possible that anywhere, except in the incurable ward of an insane asylum, could originate such a proposition as that now put forward by Senator Langford of San Joaquin. But those who question the financial wisdom of the proposed change don't understand "economy"; they are not up in "retrenchment" and "reform."

In the Langford, et al., dictionary, "Economy" (with a big E) may be thus defined:

Economy, noun: *œconomia* (Political). An opportunity to show how not to do it. A biennial chance to hurt the State.

No reflection is intended upon the University nor any part of its management nor the distribution of its funds. The able gentlemen in that institution of learning are above praise and beyond criticism. But now that "economy" is urged as a plea for the transfer of the Bureau it may in all humility be asked, "Where does the 'economy' come in?" It is but just to add that the PRESS understands that the University is not seeking the proposed addition, and is in no sense a party to the controversy. The issue is a plain one. In the interests of the miners, manufacturers and mining interests of California the PRESS maintains that, viewed in any light, it would be a business mistake to seriously entertain Senator Langford's proposition, and it is evident his bill is not in the interests of "economy," or "retrenchment," or "reform." Senator Langford has the floor.

The Mineral Lands.

The fight of the Cal. State Miners' Association against the absorption of the mineral lands of the State by the railroad companies continues to be pushed by the committee in charge of the work in this city. It is a matter of public concern, since whatever affects the miners of the State affects the material interests of the commonwealth. It is unfortunate that the committee is hampered in its efforts by the apathy or hostility of the Land Department officials at Washington, and the lack of necessary funds, which can only be obtained by general contribution, and concerning which an urgent request was recently published.

So far as possible the committee is overcoming the difficulties in its way, and reports favorable progress. When it was learned that the agent of the Cal. State Miners' Association was denied access to the Land Office lists of lands selected by the railroad company, a protest was at once filed with the Secretary of the Interior against such action on the part of the General Land Office Commissioner, and a request made that the Commissioner be instructed to comply with the just requirement of the Association's agent, inasmuch as the Commissioner had plainly exceeded his power. It is understood that the Secretary has acted favorably upon the protest.

During the week the House Committee has reported favorably on the amended California Mineral Land Classification bill and on the following resolution which had been introduced in the Senate and House:

Be it resolved by the Senate [or House of Representatives] of the United States, That the Secretary of the Interior be, and he is hereby, requested to suspend all action looking to the approval of selections and patenting to any railroad company of any lands selected under and by virtue of the provisions of the rules and regulations issued by the Secretary of the Interior under date of July 9th, 1894, until such time as Congress may dispose of H. R. 3476 now pending before the Senate and finally settle the question of granted lands.

H. R. 3476 applies only to Idaho and Montana. H. R. 8551 applies to this State, and effort is now making to secure a favorable report on it also. The committee to whom it was referred has favorably reported the bill, directing the Secretary of the Treasury to classify as soon as possible all unpatented lands in this State within the grants of the Union Pacific.

At present, Congress in both Houses is favorable to the protection of the mineral land to the miners; the Interior Department is indifferent, and the Land Office is hostile to their cause and in apparent league with the railroad officials who are trying to succeed in securing the lands before publicity can arouse or Congressional action prevent such acquisition. With one exception, the California Congressional delegation is doing good work for the State in this matter. Congressman Geary's actions in this regard may be susceptible of explanation, but appearances are against him.

This whole matter is of great importance to the entire State. The railroad people are rushing everything to head off defeat; they are backed up by the Land Office and have so far controlled the situation. In this there is no attempt at blame or bias; it is the simple statement of a fact. The question at issue now is, Shall the railway or the State have title to the 7,000,000 acres of unpatented mineral land in the State railroad grants?

The answer should be "the State." That was the answer of the U. S. Supreme Court last May, but since then the Land Department has changed the rules and regulations which justified such interpretation by the highest legal tribunal on earth, and so given opportunity for the present question to be raised.

The committee in charge of this matter is championing the miner in the case of the Commonwealth vs. the Corporation, and deserves public sympathy and substantial support.

Concentrates.

THE Keystone mill, Amador, is being rebuilt.

THE Utah independent smelter project has collapsed.

THE Redlands Mining Co. is running the Riley mill at Panamint, Cal.

SALT LAKE, Utah, men have bought the North Calder, Or., copper mines.

THE miners at the Mocars mine, Utah, are accepting stock in lieu of money for wages.

NEARLY $1000 is being daily taken from the Uncle Sam mine, thirty miles from Rodding.

A TEN-STAMP MILL is finished at Sterling, Nyo Co., Nev., and begins work this week.

THE American Cyanide Gold and Silver Recovery Co. is a new Denver, Col., corporation.

SEVEN Grass Valley miners have leased the Wisconsin mine from Lakeman & Co. for two years.

ROSSLAND, B. C., is the now Mecca of the miners along the northeastern Washington frontier.

THE five-foot Huatiagton mill at the Breyfogle mine, Nye Co., Nev., reports good results.

THE Diamond Hill gold mine, in St. Louis gulch, Montana, will have a new 40-stamp mill in April.

THE capacity of the concentrator at the Golden Sunlight mine, near Whitehall, Montana, is to be doubled.

THE excess of gold and silver export over import for the year 1893 was $40,407,160; for 1894 it was $110,841,277.

THE Anaconda company will begin next month the erection of a refinery, etc., at Great Falls, Montana, to cost $2,000,000.

IN '94 South Dakota produced $6,000,000 of gold, and it is reasonably expected that its gold mines will this year yield $8,000,000.

A PARTY OF POLES from Chicago are working the Original Quartz Hill in Shasta Co.; a twelve-stamp mill close by is kept busy at a profit.

THE *Journal* says that the new county proposed to be formed to include the Cripple Creek, Col., mining district, will be called Oro county.

A STRONG COMPANY has been organized to work 400 acres of placer ground near Blue Lakes in Idaho, about twenty-five miles from Shoshone.

IT is now credibly reported that the sale of the Iron Mountain mine, in Shasta Co., is a fixed fact. The price is stated to be $200,000.

THE Good Hope Mining Co. vs. David Jones case will, it is thought, be compromised. The company has a standing offer of $60,000 for the mine.

A U. S. PATENT to the O. & C. R. R. Co., embracing 227,049 acres of land in southern Oregon, was received at the Roseburg U. S. Land Office last week.

THE Klamath river correspondent of the Yreka *Journal* reports the discovery by four miners of "a great asbestos mine" opposite the mouth of Bark-House creek.

AT the office of the South Yuba Co., reports have come in that the break in the ditch which supplies many of the Grass Valley mines with water is fully repaired.

NEW MEXICO'S mineral output for 1894 has not been officially announced, but reliable data show: Gold, $1,500,000; silver, 1,250,000 ozs.; lead, $80,000; copper, $50,000.

JOHN LANG has sold a one-half interest in the Lost Horse mine, twenty-five miles from Indio, Cal., to D. Sheedy, president Globe Smelting and Refining Co., Denver.

J. AND J. H. LONOMAID, lessees of the E. & E. mines, Baker Co., Or., have leased the North Pole mine, adjoining. The E. & E. has twenty stamps and the N. P. ten.

THE Hecla Consolidated M. Co., at Glendale, Mont., has paid dividend No. 135 of one per cent, $15,000, making the total dividends up to date paid by this company $2,025,000.

THERE are 400 stamps running in Gilpin Co., Colorado. There are over 700 available. Another 100 have been recently added, one-half of which have the rapid-drop motion.

THE Shasta *Courier* says it is not unusual this season to hear of miners picking up considerable coarse gold in old diggings that have been washed over by the heavy rains.

THE Dunsmuir *News* says the snowfall at that place has been a little over twenty-seven feet, about thirty inches falling during last week. In addition there has been a rainfall of twenty-eight inches.

THE *Silver State* says the Imperial quartz mill, mill site, office and assay office at Kennedy were recently sold for taxes and purchased by H. Warren for J. R. Benton, C. E. Kennedy and W. L. Wilkinson.

FOR the year ended November 1st the Anaconda Company's smelters treated 747,500 tons of ore from the mines of Butte, Montana. This ore produced 75,915 tons of matte, of which sixty per cent was copper.

THE Old Glory, Arizona, mine has let a contract with the Joshua Hendy Works to put in forty stamps. The Griffin mills have not been satisfactory to the company and they have decided to put in stamps.

THE Mining Bureau bill in British Columbia has been amended to provide for a Provincial Mineralogist who shall take the place of the Deputy Minister of Mines. The bill is receiving lively support.

DURING 1894 West Kootenai shipped silver ore to the value of $400,000; gold, $170,000; lead, $180,000; copper, $15,000—a total of $770,000. The silver ore assayed over $100 a ton, with bar silver at sixty cents an ounce.

NEW YORK men are reported about closing for the purchase for $150,000 of the old Washington mine at French Gulch, Shasta Co. It has paid continuously for the past twenty-five years, and a ten-stamp mill is now running.

As affecting placer miners, this is Hoke Smith's latest: "There must be a discovery of mineral on each twenty acres in the placer location of 160 acres made by an association; and such a location of that amount, based upon a single discovery, is void, except as to the twenty acres immediately surrounding such discovery." A former decision covers, substantially, the same ground.

THE Stickle Company has incorporated. Principal place of business, Angels Camp, Calaveras county. Capital stock, $100,000, with the following directors: C. D. Laine, G. Stickle, E. Stickle, T. T. Lane, W. Garrare.

THE smelter at Barker, Montana, was burned down last week. It was built in 1881, and was kept in operation until silver and lead fell off in price until there was no profit, when it was closed. The origin of the fire is unknown.

THE *Record* says: A Denver company is organizing for extensive operation in the mining fields of Alaska. It is proposed to take a large number of Colorado prospectors up there and establish them at placer mining and lode hunting.

THE Canadina Pacific, or an interest friendly to the Canadian Pacific, is looking about for a smelter site. One element is pulling for Nakusp. Another element favors locating the smelter at one of the falls on Kootenay river, below Nelson.

AT the Golden Cross mine, Ogilby, San Diego Co., the forty stamps will soon give place to 100 stamps. Thirteen miles of pipe bring water from the Colorado river. The twenty-stamp mill at the Cargo Muchacho, in that district, is also kept busy.

A PRELIMINARY ASSAY on the ore of the Jeannette mine, Ainsworth, B. C., showed 78 ounces in silver and 14 per cent lead. The ore represents the entire vein, which is five feet wide from wall to wall. It will concentrate about five tons into one.

PAPERS published in mining counties of Idaho are giving hearty support to the proposition to amend the mining laws of the State in such a manner that locators will be required to show their good faith by doing ten feet of work within a reasonable time after location.

THE Sierra Buttes Mining Company, which recently bought the Mammoth mine at Jacksonville, Tuolumne county, for $80,000, is developing the property. A crosscut recently made discovered a rich parallel vein, the existence of which was not suspected by the former owners.

THE North Fork drift gravel mine, in Sierra county, is reported doing well. The tunnel is now in over 700 feet, and is being driven at the rate of two sets a day. Fourteen men are employed, and they are making good headway, and expect to reach the old Uncle Sam incline by next August.

THE Morning Glory mill, Turkey Creek, Arizona, is dropping stamps regularly, the plant being run by the men who have been in the employ of that company, and having a business difference with the proprietors. They are said to be making money and that the mine is good property.

THE latest candidate for mining favor in the treatment of refractory ores is the Brind-Nicholas process, which will be operated in the United States by the Brind Extraction Company. It is already working in Australia, a 100-ton plant now being in operation in one of the mining districts of Victoria.

THE Rosemont, Ariz., copper mines have closed down. Very little development work has been done on the property, and it was found to be a piece of folly to try to maintain an eighty-ton smelter running on surface ore. This is but another instance of the uselessness of erecting reduction works before having a mine.

THERE are three giants running night and day within three miles of Grants Pass, Or. Two of them belong to Wickstrom & Corliss in the Dry Diggings and the other to Spencer & Gunning on Bloody Run. Several acres will be torn up and sent into Rogue river before the water gives out, and the indications point to a profitable cleanup.

THE patent issued the Montana Mining and Reduction Company on mineral entry for lands in the Helena, Mont., land district, involving the Ida, Emma, Cleveland, Dandy, Bismarck, Star, Saratoga and Handy Lode claims, has been cancelled by the Interior Department. It is charged the lands were non-mineral and the entry was fraudulent.

THE Kootenai Hydraulic Placer Mining Company, which has been operating all the way along the Pend d'Oreille river from Boundary City to the mouth of the Salmon river, has turned its affairs over to the Kootenai Water Supply Company, which will take charge of all the placer mining operations of the former company and work them on a royalty.

L. THUILLIER of Lewiston, Idaho, is operating at the mouth of Alpowai creek a machine which he says will save nearly all the fine gold that exists in the sand along the Snake and Clearwater rivers. He claims that "while a rocker will not pay over 35 cents per day, this new and comparatively simple device pays from $3 to $5 per day, according to the ground."

THE Debris Commission have granted hydraulic mining permits to Robert, James and John Blair, proprietors of the Mitchell hydraulic mine; El Dorado Water and Deep Gravel Mining Company, proprietors of the Henrietta mine; Rollaud & Vanderberg, proprietors of the Epley mine; and Hancock & Daly, proprietors of the Last Chance mine. All of these mines are located near Placerville, El Dorado county.

A BILL has been presented in the Washingtou Legislature to create a Mining Bureau, to consist of three commissioners, representing the different mining sections, their duties being to gather all the information of the mineral interests of the State. Repositories are to be established at Seattle and Spokane, where ores may be left and maps, drawings and copies of assays placed on file.

THE Mammoth mine, near Middle Bar, Amador Co., is reported sold to an English company for $30,000. Several kidneys of black metal carrying a heavy percentage of gold were formerly taken out, aggregating in value nearly $100,000. Two shafts were sunk—one to a depth of 800 feet—and a tunnel driven from a point fronting the Mokelumne river to tap the latter, wherein work has been done for short periods since regular work was suspended.

AT the recent banquet of the American Assocation of Mining Engineers at Bridgeport, Conn., W. D. Bishop created considerable amusement by reading a prospectus of "The Woodland Gold Mining Company" of 4894. The prospectus recites that the company has discovered and purchased the precise spot where were buried the wealthy New Yorkers of the olden time. It says that it has been calculated that the remains of no less than 9,500,000 people were buried on the ground that the company controlled, and that as at the time, in the nineteenth and twentieth centuries, when they were buried, it was the fashion to fill the teeth of the people with gold to an average amount of $7.50 to each person, no less than $71,250,000 worth of gold was buried in the territory, which would be recovered at a small expense. The company expected to make a net profit of at least $40,000,000 on a small outlay.

LEONARD SAWYER, of Buffalo, N. Y., has bonded the Palmetto, Arizona, group of mines for $90,000 for six months. They are in the Pinnosa mountains, on the old Ehrenburg road, and are known as the cement deposits, being covered by placer locations, and comprise in number six claims. They had been known for several years, on account of their richness and the peculiar geological conditions attached to them. The claims have been thoroughly and systematically prospected, and in every test made the same uniform results have been given in free gold.

LIVELY times are prophesied at Coulterville, Mariposa county, next season. Large quantities of machinery are being received and put in place. While there is no demand for any more laborers, there being a good supply in the vicinity, it is expected by April or May next several hundred men will be needed to carry on operations already planned out. Coulterville will soon begin to put on the appearance that the town had in the old days of California mining when twenty-dollar pieces were as plentiful as dollars are now and were more evenly divided.

A NUGGET, not gold, but representing a chunk of that metal, and worth, if pure, $25 or $30, was recently swapped to a Hassayampa, Arizona, man for a horse. A Prescott assayer made an acid test of the metal and pronounced it oroide, or a composition of base material. The acid bit at the touch and copper colors were instantaneous, but strangely enough the metal resumed its golden hue as soon as the acid had been wiped off. It had the appearance of having been smelted in a forge; even the ray marks in which the amalgam had been wrapped were apparent. It was this characteristic that fooled the Hassayamper.

IT has always been supposed that the Sterling Mining Company, in Josephine Co., Oregon, owned all the mining ground along the creek for a distance of three miles and more, and that this ground was covered by their numerous purchases. It develops, however, that this is not the case, and that the company only owns a narrow strip along the creek, and that this strip does not cover the old or back channel, but a part of the distance, and that a large amount of the rich mining ground was vacant. Some parties in searching the records discovered this fact and located the vacant ground—some four hundred acres.

THE millmen of the Horn Silver, Utah, concentrator are reported suffering from a new complaint caused by the use of the water in the mills. The water is used over several times and becomes strongly impregnated with arsenic, antimony and other like poisons, and as the men are required to occasionally immerse their hands in this, it seems to penetrate the skin and produce sores similar to felons. When they go to the hospital to receive treatment these men are told that the sores are produced by poisons and are not felons. Like lead poisoning, it is a natural consequence of the handling of this class of ores.

A. R. HAMMOND, who headed a party of sixty miners and assayers to South Africa last May, writes from Buluwayo the reverse of encouragingly. Fevers, tigers, hostile Zulus, lions, desolate country, etc., interfered considerably with the success of the expedition, according to a letter to the *Chronicle*. He concludes by saying: "The Californians of my expedition have so far located 220 mines, and have placed on the London market 125 square miles of good land in conjunction with the other properties. Messrs. Bumohom of Pasadena and Ingram of San Francisco will leave for London to see Cecil Rhodes for the purpose of forming an expedition to open up the country on the headwaters of the Zambesi during the coming year."

THE Assembly Committee on Mines and Mining has before it two bills for consideration. The first, introduced by representative Holland as Assembly Bill No. 90, provides that all cages, buckets, skips and other apparatus used in mines shall be provided with a safety. This applies to mines where the shafts are deeper than 300 feet and where twelve or more men are employed. In addition, the mining company must sink another shaft or construct another tunnel to connect with the main working shaft of such mines as a means of escape from underground accident. Failure to comply with provisions of the law will render the individuals or corporations liable jointly and severally for all damages to miners or their heirs. Tibbits' Assembly Bill No. 294 adds a new title to Part 2, Division 2d, of the Civil Code, providing that supervisors may divide their county into mining districts or establish such mining districts therein as they shall deem necessary.

Personal.

JOHN VASS is the new superintendent of the White Swan M. & M. Co., Baker Co., Or.

CHIEF ENGINEER JOSEPH TRILLEY, U. S. N., has been ordered to the Olympia and will for the next year direct the operation of her machinery.

F. E. BRIGHTON has succeeded G. V. Gray as superintendent of the Gladstone mine, near French Gulch. The Cleveland, O., men who own the property have spent about $250,000 in developing the property.

J. J. BYRNE has been appointed general passenger agent of the Atlantic & Pacific and Southern California, with headquarters at Los Angeles, to take effect Feb. 1. The office of assistant passenger traffic manager of the A. T. & S. F. is abolished.

Obituary.

NAVAL CONSTRUCTOR ARMISTEAD, who was injured by the hawser parting while removing the case on the caisson from its position at the drydock at Mare Island on the afternoon of the 26th, died at the Naval Hospital at seven o'clock the next morning.

WM. IRELAN, SR., a California pioneer, died in this city on the 27th ult., in his 84th year. He founded the first shipping yards in this city. Shortly after the wreck of the Golden Gate on the Manzanilla coast, in '62, he recovered $800,000 of the million and a half on that ill-fated steamer, of which his share was $250,000. He engaged in mining in Sierra and Placer counties, and did considerable toward developing mines there and elsewhere in the State.

The U. S. Geological Survey.

To the Editor:—The watchword of our present generation is "fair play." The football enthusiast grows vehement in denouncing an unfair decision, and a great nation often stands quietly overlooking with war ships inferior nations engaged in strife, and proclaims "neutrality," or, putting it more strongly and more commonplace, prevents one from taking undue advantage of the other.

The writer, as a subscriber to the *Engineering and Mining Journal*, has noticed in the two last issues many remarks upon the work of the U. S. Geological Survey.

While feeling perfectly friendly toward the *Journal*, I cannot but feel that the Survey is not receiviug "fair play" in the receut criticisms. Having also served eight years in the topographical corps of the Survey, a few remarks are now presented, which cannot be said to be influeuced by personal feeliug or any possibility of preferment by the departmeut, as I am now busied in the private practice of mining engineering in San Francisco.

Referring first to the letter of Dr. Persifor Frazer in the *Journal* of January 5th, one caunot but be struck by the lack of iutimate knowledge displayed by him of the work of the Government surveys. Dr. Frazer says "that a geological survey should be purely scientific and only incidentally economic, and should not try to make topographic maps or compete with the older or more valuable institution whose work of this kind contrasts favorably with any heretofore accomplished in the world."

If Dr. Frazer will kiudly state how it is possible to make a *geological map* without first having delineated a *topographical map*, such information will be welcome to those interested in scientific research, and he should also mentiou what institutions outside of the Geological Survey (which was formed in 1878 by combining the Powell, Hayden and Wheeler surveys) aud the various State surveys have made topographical surveys. If the U. S. Coast and Geodetic Survey is meant, the public well know that the minute aud correct work of this Bureau is confined to the immediate vicinity of the Atlantic, Pacific and Gulf coasts to aid the mariner in navigating harbors and elsewhere for coast defenses. The "Coast Survey" in the interior is simply a "geodetic survey" to counect ocean with oceau by triangulation.

The investigation of irrigation questions and ganging of streams is only a small matter to wind up the irrigation inquiries begun some years ago by the Geological Survey.

Director Walcott has himself answered the question whether "euginеers, chemists, etc., of the Survey receive fees while drawing Government salaries" by a decided "No," and so has his predeeessor, Major Powell.

There thus remains to be discussed the question, "Should it be a bureau of research and report upon questions of mining, metallurgy and statistics?"

For many years past the Survey has made detailed and valuable maps and reports of special mining areas and published annually a report upon the "Mineral Industry of the United States." This work, under the direction of Dr. David T. Day, has given general satisfactiou, the only criticism being that the Government printing office has been so crowded as to prevent these volumes from being issued promptly at the close of each year.

The *Engineering and Mining Journal* has also published for two years past the "Mineral Industry and Statistics of the World"—a very valuable work, but, having such a wide field, it cannot be, in that portion referring to the United States, as detailed or accurate as the work uudertaken by the Geological Survey, which makes special report of each mineral product and gives further information of benefit to the mining operator in this country.

There is no doubt but that the work of the Survey could be incorporated each year in the book published by the *Journal*, which latter in its present conditiou must necessarily be somewhat approximate.

The *Engineering and Mining Journal* of January 12th contains a letter from Mr. John F. Blandy, of Arizona, which, upon reading, appears more serious. The only answer to this criticism is that it is well known that some of the topographic work credited to the Geological Survey has been compiled from other surveys, with a desire to prevent duplication and economize time and money. And again, some of the work done in the earlier years of the Survey has been drawn on too small a scale for detailed geological investigatiou, and will have to be done over again. This refers particularly to Utah, Nevada and Arizona.

Another criticism brought out by Mr. Blaudy is that the U. S. Geological Survey is gradually crowding out the State Surveys. In Massachusetts aud New York both States joined forces and paid half expenses to make a topographic aud geological map, the field work performed by the well trained corps of the Geological Survey, and the management under a commission of State and Government officers. Why eannot the same plan be followed by the other States to the advautage of correct and economical work?

There is no doubt but that the work of the Geological Survey is open to criticism, but to an interested observer the maiu object should be to give all the practical information possible—not to publish such senseless and bitter criticisms, but to preveut the Survey from becoming too technical.

Government maps should all be drawn to oue scale, and special maps made on large scales only in mining regions and other points where detailed geologic investigation is necessary.

The Land Office publishes township maps on a scale of two miles to one inch, and, in view of the large amount of country yet to be mapped by the Government, this general scale is adequate. The topographical maps should have township corners placed upon them, so that the practical civil and mining engineer can locate himself in a more direct and recognizable manner than by polyconic projection.

If the *Engineering and Mining Journal* desires to be a frieud to its clients, why should these childish quibbles and criticisms be published? Rather let the *Journal* advocate *centralization*. The differeut surveys, the U. S. Coast and Geodetic Survey, the Topographical and Geological Survey, and mining statistics and the Land Office Survey, should all be placed under one jurisdiction, and this "Burcau of Surveys" could pass judgment on all the work heretofore performed and see that future work is drawn to one adopted scale. Each separate branch could theu pursue its course without duplication or iuterference, aud, all having "fair play," a result would be accomplished redounding to the credit of accurate and economic work. Mark B. Kerr.

San Francisco, Jan. 25, 1895.

From Placer County.

To the Editor:—Perhaps there are but few spots iu California to-day that have become less attractive and almost dropped completely from the memory of the early gold hunters, and so little known of to the preseut popnlation, as this aud similar localities situated iu the foothills and the Sierra Nevada mountains themselves. Every facility is here offered to the practical and economical miner to push the work with advantage at all seasons of the year, under the most favorable circumstances, for which he will be liberally rewarded in amounts to warrant him, or them, to continue the work. Very little developing in a practical way, outside of scraping over the surface, has been done. The "old timers," or pioneer gold hunters, what few there are still alive in these localities, have but one idea, together with their early acquired habits of the use of liquors and extravagant way of living and taking things in a slow and easy-going way. They are looking for and trusting in the future for a revival of the early days of excitement and hilarious living, but do nothing towards helping to develop the mines to correspond with the present epoch. They delight in congregating at the grocery, where cheap liquors and tobacco are dealt out, sometimes on tick, in a large back room, warmed up and provided with cards, etc., and recite to strangers what they used to do, etc. The younger men hereabouts easily fall into the old worn path and become in time the same as their predeeessors. It is a repetition of history, less the gold excitement. Nothing is done to get ahead of actual wants in a rude cabin with one room for all purposes. It is deplorable in the extreme, and something ought to be doue to change the methods and systems of such non-progressive people. Our newly elected member of Congress, Grove L. Johnstou, who was such a bitter enemy to hydraulic miuing in the anti-debris times, has promised to obtain relief iu way of appropriations for restraining dams, but delays cast gloom over the prospects. However, we anticipate the best results through his promulgations at Washington for the benefit of the mining community.

Why go to South Africa and Australia gold hunting when such spleudid opportunities are here offered under California's genial climate and its protective laws? Those apparently new gold fields have already put on the dyiug garb, aud word comes that it is overdone and overrun. The writer put in several years iu the Andes in South America, but under less favorable circumstances, conditious and climate than our own Califoruia offers. Let us with one accord believe in and push the mining interest of California to renewed activity.

Aside from the very promising miuing outlook in this locality, it is one of the most picturesque sections of our State, abounding in pure water, air and other life-giving elements. A more beautiful place for a tourist's hotel seldom eau be found with such advantages and attractive scenery. It far surpasses other resorts of noted reputation for summer visitors for health and pleasure. I've seen them all. Yours, etc. Traveler.

McKinstry Ranch, Placer Co., Cal., Jan. 26, '95.

Astronomers claim that there are over 17,500,000 eomets in the solar system alone.

Reporting on Mines.

To the Editor:—Two reports are called for: one elaborate and in detail, that is to be printed with views interleaved aud is intended for the eastern aud foreign market; the other concise and emphatic, for the experienced mining operator. A miuer onee requested me to show an elaborate report, by a celebrated expert, to a large operator. The operator waded through the report, until he got fairly into the geology, when he handed the report back to me with— "D—— such rot! If the gold is in the vein all the rocks this side of Hades won't take it out, and if it aiu't there they wou't put it in! Tell him to sample his vein, measure the width and length of the ore shoot, and report; and tell him to frame this report or use it to start his fires with."

The professional expert may claim that if the average miner were to report on his mine, he, like the haugman, would be his owu "neckspert." However, the practieal, experienced miner, owning a prospect, can give a description as satisfactory to the California miuing operator as the expert, if he will be honest with himself, and not, from force of habit, involuntarily select, in sampling, only the rock from the richest portion of his vein.

The average buyer requires the location of the mine, its situation as to roads and water power, the title, character of the ore: i. e., free milling or otherwise, average width of the veiu, length of the shoot with sketch showing development, average sample of the vein, a fair-sized piece of the mineralized portion of the veiu, and, last but not least, reasonable price aud terms.

Many of the reports issued remind one of the old attorney's advice to the young lawyer: "If the facts are in your favor bring them out and stay by them; if they are against you avoid aud talk all around them." If the mine is a good property, a few facts, plainly stated, will suffice; if it is not "in sight" a great amount of sophistry will be required to conceal it. California miue operators buy either on their own judgmeut or that of some one in their own employ, and only want the main facts to determiue whether they will investigate or not. Once they see a mine what they have previously read has no effect on the samples they secure aud on the value of which they buy or decline. Respectfully,

E. H. Schaeffle,

Murphys, Cal., Jan. 19, 1894. Ex. U. S. M. E.

In the Jicarillas.

To the Editor:—The mining camp of the Jicarillas, located in Lincolu county, New Mexico, is attracting the attention of miniug men on account of the formation here, which is so strictly of a volcanic nature as to prove beyoud a doubt that the formation of the ore bodies of the district was from the heat and eruptions of numerous volcanoes, the chimneys of which can yet be traced on the ground.

Unlike most miuing districts, the district of the Jicarillas is not one in which the leads, generally speaking, are of value. True, many are the locations on small veins of high grade ore, yet invariably do they find on sinking that the ore pinches out, aud they lose the treud of the vein, only to be confronted by country rock on all sides.

The properties which cause the most talk among mining men are located in what is called in the district "iron blowouts." These blowouts are chimneys of ore coming from the bowels of the earth, and for 150 feet or more on the surface they are choked up by volcanic ashes and debris of different kinds, showing that the ore at one time was exposed, but that it either settled or else the ore in coming out failed to reach the surface aud as a consequence the opening thus left was filled up with foreign matter.

From the above it will readily be seen that the camp of the Jicarillas is no camp for the poor man, for the ore lyiug so deep makes it impossible for a man to open up a mine unless backed by money, and lots of it.

Geo. J. Weishar is the owner of two claims, which show up some good metal in the walls near the surface, but there is no ore body in sight, and it will take several feet of developing work to open up any pay on the properties, both of which are on blowouts.

Jno. Duncan is locator of the Silver Cup, a claim which ten feet from the surface assays $10 in gold and holds promise of leadiug to a large ore body.

Harry Comrey, W. W. Fitzpatric, E. L. Ganne and several others own claims which are now lyiug idle on acconnt of the lack of capital to develop them.

P. C. Bell, owuer of the Elizabeth, is the only miner in camp who is developing his claim and putting in any great amount of money. He states that there will be a mill on the claim in the very uear future. "Jics."

Sixty per cent of the coal used in making gas in Chili comes from Australia. Englaud furnishes a little cannel coal and the remainder is from native lignite mines.

The Removal of Clay from Iron Ores.

Clay or adhesive earthy substances prove about the most difficult matters to deal with in regard to iron ores, for while moisture and insolubles are largely increased, thus reducing the metallic content of the ore as received at the furnaces, the difficulty of removing adhesive matters is considerable, particularly when it is inclined to form slimy balls when moved. Some clays disintegrate easier than others, while some become almost glutinous when wetted, and as they are always more or less moist when raised, they cannot be dealt with in a dry state, however desirable a dry process would be. Friable or sandy clays are easily dealt with, as they disintegrate readily in an ordinary revolving washing cylinder having internal blades, as in the case of a clay-washing mill; but if the grains of ore are much larger than eggs, this cannot well be done owing to the continual stoppages, and to the repairs which become necessary through the knocking about of the ore grains. Where the grains are large, it becomes necessary to use a nearly horizontal cylinder of considerable length, spikes projecting from the sides to prevent the wet material forming a ball, by checking the regular rolling of a large mass. A regular flow of water must pass through the cylinder to remove the fine matters as they become separated, and the larger parts will travel out of the cylinder in the ordinary way adopted to these apparatus. It is not readily possible to crush the large grains before washing, as the crusher would probably ball the clay in such a way that subsequent washings will fail to cause disintegration. So far as possible, the men engaged in mining this class of ore should separate the larger grains of metal from the bulk, and this they will usually do if an increase of a few pence per ton is given for large clean grains for loading.

Ore which is full of tenacious clay readily separable in water, but which requires some amount of soaking, can, if water is plentiful, be well and cheaply cleansed by turning a jet of water on it and washing the face of a heap, the water and clay in suspension being carried away in troughs, while thecleaned ore is loaded up for further separation in jigs or into wagons for sending away to the furnaces, as the case may be. By carefully laying out a floor for this work, and by having a moderate head of water, large bulks of clayey ore can be treated very cheaply in this way, while if there is only a small quantity of fine sandy ore, the loss in metallic value will not be great. Special washing troughs of perforated steel plates might also be used if preferred, and in these the ore might be readily prepared for market, as only that which was perfectly cleaned need be left in the troughs, the water and dissolved clay passing through the plates.

Very tenacious clays are best washed out with a more or less powerful jet of water, and in this case the troughs just described are very useful indeed, as they permit of the removal of the clay at once. The cost is more in this case than with more friable material, but conditionally on the ore being placed in the troughs, or in a bin communicating with the troughs, say, in one-ton lots, the water thoroughly removes the clay before another lot is shot in the washing receptacle.

Gold Mining in the Transvaal.

During the second quarter of 1894, 823,1"0 tons were milled by 2922 stamps on all the gold fields of the South African Republic, the average number of days on which milling took place being 78. Witwatersrandt, not including the Nigel district, represented 725,394 of this total tonnage. During the same period 882,937 tons were raised. The average number of tons crushed per stamp per diem was 3613, being highest at Klerksdorp, 4659 tons, and lowest at De Kaap, 1971 tons. The gold produced by ordinary milling operations totalled, during the same period, 369,905 ozs., worth $6,653,545, the yield per ton being on all the fields 0.449 ozs., and the value $8.08. Out of the above total Witwatersrandt represents 327,291 ozs. During the same period 759,828 tons of tailings were worked, of an average assay value of 0.270 oz. per ton. They were the richest at Heidelberg, 1.217 ozs. per ton, and the poorest at Klerksdorp, 0.223 oz. per ton. From them were produced 173,766 ozs. of gold, or 0.229 oz. per ton treated, showing 0.041 oz. left in the residues treated. The value of these was 516,577, or $3.38 per ton; 5735 tons of concentrates were produced and 4652 worked. The average assay value of the untreated ores was 8.348 ozs., and of those operated upon 3.912 ozs. per ton. The De Kaaps were the richest, 7.741 ozs. per ton, those of the Witwatersrandt averaging 3.318 ozs. The total output from concentrates was 18,632 ozs., worth $353,675. The total gold production of the State from April 1 to June 30, 1894, was 563,222 ozs., of a monetary value of $9,605,840.

SCENE ON THE RAILWAY IN THE CALIFORNIA MOUNTAINS.

A MOUNTAIN GORGE IN ITS SNOW MANTLE.

THE cash value of a locomotive averages $10,000, and there are now in use on the railroads of the United States about 35,000 locomotives, representing a total investment of $350,000,000. The Pennsylvania railroad stands at the head of the list with 1625 locomotives. The New York Central is not very far behind with 1200 locomotives.

THE use of the telephone on Australian sheep ranches is becoming common. Its employment is mentioned on the Clark ranch in Montana, where all the sheep and shepherds are watched and handled telephonically by means of six stations, all communicating with a central point.

On the California Mountains.

Herewith is illustrated one of California's resources which is not usually counted among the possessions of the State, and that is the exceptionally fine snow mantle of our mountains. It is an exceedingly picturesque feature of the State, but one which is as little appreciated as it is talked about. It is only when it asserts itself, as it is now doing, in the stoppage of overland traffic, that the public generally notes its presence. It has not yet caused us the inconvenience of earlier years, when days multiplied into weeks before the trains could break through the mountain blockade, but that is no fault of the snow. It is all up there ready for the blockade business, but the machinery for its conquering is much superior to that of former days.

The engravings are characteristic mountain scenes this month. One shows a site on the overland line where the snow has well nigh buried the small village, while the railway runs between banks twenty or thirty feet high made by the powerful rotary plow in keeping the rails uncovered. The man standing in pensive mood on the railway track is not waiting for the train. He is merely thinking what a fool a photographer must be to prowl around in such weather.

The other scene shows the unbroken solitude of the snow-clad mountain region away from settlements and railway lines. The gorge is well nigh choked with snow, and the tall pines, which in the distance seem like the trees of the toy shops, are in many cases half buried. It is a scene comfortable to contemplate when one has his feet on a warm fender.

The Truckee *Republican* says: "Truckee presents an appearance that is at once novel and picturesque. To the average Californian who is accustomed to seeing green fields and blooming flowers, it is a marvel. The whole town is enwrapped in the emblem of purity to the depth of several feet, while icicles in their crystal splendor adorn the eaves of every house. The rotary snow plow, as it drives up and down the track throwing a stream of snow a distance of a hundred feet or more, is a sight that would interest the most stoic observer. In order to cross a street in Truckee, one must climb from the sidewalk on steps in the snow to the street and then descend on the opposite side. People on one side of the street cannot see those on the other side. In many places the snow is so deep around the eaves of the houses that it has to be shoveled away from in front of the windows in order to allow light to enter the house."

IN some recent experiments, says A. C. Swinton, Mr. J. C. M. Stanton and I found that, employing a very strong electromagnet, a piece of ordinary white asbestos mill-board, about $4x3x\frac{1}{16}$ inches in size, and weighing one-half ounce, was easily lifted through a vertical distance of one and one-half inches, and when in contact with the magnet pole the asbestos pole would support four ounces in addition to its own weight. Lumps of hard asbestos, such as are used in gas fires, as also pieces of soft asbestos cotton packing, were also strongly attracted, and when some of the latter was placed on the magnet pole and the current turned on and off, the individual fibers could be seen in movement. Further, it is quite easy to permanently magnetize a piece of asbestos mill-board, when it will behave exactly as a magnet both in attracting and repelling a compass needle. The principal constituents of asbestos are stated to be magnesia, silica and alumina, with some oxide of iron. No doubt it is to the presence of the last-named substance that the magnetic qualities are due. White asbestos is, however, understood to contain but small traces of iron—much less than the colored varieties—and consequently the degree to which it is magnetic seems surprising. In any case, it may be well to warn experimentalists that asbestos is not a suitable substance to employ in connection with delicate instruments where any unsuspected permanent magnetism might be productive of serious error

Some Practical Results.

TO THE EDITOR:—I have read with much interest the articles on the "Limitations of the Stamp Mill," and believing that some results obtained by me in working in the line indicated by Mr. Phillip Argall in his discussion of Mr. T. A. Rickards' paper would interest some of your readers, I submit the following:

The value of the ores here is almost entirely in the sulphides—iron, zinc, copper and lead; hence the end sought in designing a plant was to crush sufficiently to clean the quartz and avoid slimes as far as practicable. The fact that the concentrates were to be treated by chlorination was also considered. For a crusher a Tustiu pulverizer is used, and a McGlew concentrator handles the pulp.

About fifty tons were crushed and concentrated, with no plates for catching free gold. A number of tests of pulp and tailings were made from time to time, the samples being taken with care. The results invariably showed ninety to niuety-four per cent saved in the concentrates, so long as a forty-mesh screen was used. A thirty-mesh showed an additional loss of ten per cent, which was remedied by replacing the forty-mesh.

A short piece of amalgamated copper plate has since been placed directly under the discharge of the mill, and while saving practically all visible free gold, does not appreciably increase the total percentage saved. Some small lots of custom ore have been worked. The results of one lot show the following figures:

4¼ tons of ore worked yielded of free gold, 2 oz. 8 grs.	$ 29.00
Concentrates, 1200 lbs, containing	124.23
4 tons (scant) of tailings, containing	5.80

The assays of concentrates showed—

Silver	8.5 oz., worth $ 6.12, at 72c. per oz.	
Gold	8.50 oz., worth 200.93	
		$207.05 per ton.

Tailings averaged—

Silver	.36 oz., or	$ .25 per ton.
Gold	.07 oz., or	1.45 per ton.
		$1.70 per ton.

These results were obtained on undecomposed ore, and in handling a ton in from six to eight hours. On decomposed ores, with forty-mesh screen, the results have been a trifle less thau when worked in stamp mill or arrastra. E. L. BALLOU.

Falls Minc, Igo P. O., Shasta Co., Cal., Jan. 26, '95.

Geographical Society of the Pacific.

The Jauuary meeting of this society was held last Tuesday evening at Uniou Square hall. Henry Lund, Consul for Norway and Swedeu, who has receutly returned from a vacation in Europe, read an interesting paper on the "Lost Relics of the Jeaunette Expedition." These relics, it will be remembered, were removed by Lt. De Long's party from the steamer before she went dowu, off the Siberian coast, and abandoned on an ice floe when the start was made for shore. The floe carried them across the Polar sea, dowu the east coast of Greenland, and they were picked up in Baffin's bay after three years' voyaging. The Governor of Greenland sent them to Copenhageu where they were stored and finally thrown away as worthless. Their value to scientists is, that they showed the existence of a current crossing the mysterious Polar sea, that unknown region which has baffled so many well-planned expeditious. Prof. Nordenskiold is now up there with a specially built vessel, in which he will seek to reach the point where the Jeanuette was lost, and thence drift with the icebergs over the course the relics took, coming out near Greenland. Mr. Lund was followed by Professor Davidson with a paper ou "The Military Status of China," by Rev. Gilbert Reid, Chief of the Missiouary Board at Shanghai.

The uext meeting will be addressed by Professor J. M. Schæberle, of Lick telescope fame.

ELECTRIC CLOCKS are becoming familiar everywhere. The process by which they are set is the inveution of W. F. Gardner of Washington, D. C. Every day in the year, at five minutes before twelve, the Western Union Telegraph Company stops all business and throws open all circuits. At noon precisely a button is touched in the Naval Observatory at Washingtou, and an electric spark flashes to all parts of the country, causing the hands of 100,000 clocks to point to the hour of twelve. The same spark causes time-balls to fall at all seaports along the Atlantic and Pacific coasts. These time-balls are for the benefit of marines, enabling them to regulate their chronometers.

THE largest permanent store of coined money in the world is in the imperial war treasure of Germany, a portion saved for emergencies from the $1,000,000,000 paid by France after the Franco-Prussiau war aud locked up in the Julius tower of the fortress of Spandau. It amounts to the value of $30,000,000.

THE best burglar-proof safes are made of alternate layers of hard aud soft metal, which are welded together. This combination will not yield to either drill or sledge-hammer.

Public Expenditures.

There is a direct relationship between prudeuce iu public expeuditures and political morality; and by those whose eyes are open to the deeper significance of things, this fact appears the most important of the many cousiderations supporting the reform effort at Sacramento. Reasonable appropriations for legitimate purposes would make the State service a business instead of a political organization aud would preveut the ten thousand petty corruptions which destroy the dignity of official life and degrade to a greater or less degree the character of everybody connected with it. Thus a system of reckless expenditure first impoverishes the tax-payer and then vitiates our public service. It is not too much to say that every dollar unwisely spent in an economic sense is a dollar viciously spent in a moral sense. It is the illegitimacy of our public expenditures which makes the scene alike pitiful and shameful just now to be witnessed at Sacramento. The State Capitol swarms with place hunters of every age, conditiou and sex—present not because they have any genuiue taste or capacity for public service, but because it is kuown that effrontery, importunity and petty bribery may open to them small streams of illegitimate profit at the public cost. There is now in session at Sacramento a legislature elected in the midst of hard times and pledged to economy; but in spite of these facts, it is spending $728 per day for clerk hire. Of course, everybody knows that this is unnecessary and without excuse; that the legislature would be better off if it would go about its work unannoyed by a swarm of sinecure employes. It is illegitimate, it is vicious—but it goes with the system and will continue until the system shall be superseded by another founded upon and limited by the necessities of the public service. Another fact very notable at Sacramento just now is that funds appropriated for the promotion of certain large public intents are being speut to secure still further appropriations. Thus, State money given into the hands of commissions is being used to perpetuate the life of these commissions rather than for the purposes for which it was (with rather more than less impropriety) originally designed. It might further be shown how there is at Sacramento a powerful lobby of present officials, of prospective officials and of political managers united in a defensive fight for the system as it now exists. These facts illustrate the connection between public extravagance and political immorality; and they afford the best possible reason —a reason even more vital and profound than the purely economic motive upon which the reform movement is founded—why the whole system should be swept out of existence. Does anybody suppose for one moment that, if State appropriations were given only to legitimate uses, and if places and salaries were limited to legitimate service, that the gang which now discredits the State and degrades itself would be found at Sacramento?

A DENVER MANUFACTURER who recently returned from a business trip to Mexico, explains to the *Rocky Mountain News* why American trade with Mexico is rapidly falling away. He says the reason is the high rate of exchange made necessary by the difference in the value of the dollars of the two couutries. Relatively to commodities, Mexican dollars are the same in value as they were before 1873, while the American dollars have doubled in value. That is, a ton of wheat or a bale of cotton will command as many dollars as ever in Mexico, while they will command only half as many in the United States. The result is that when a mining or other operator in Mexico purchases a plant of machinery in the United States, say at $2500, he is compelled to pay $5000 for it in his own money. The difference is the exchange rate between the two countries. Mexicans are getting very tired of this, with the result that they are not only curtailing foreign purchases, but are rapidly, under the protection which this high rate of exchange affords, building up manufactories of their own and becoming independent of the United States and Europe.

The statement of the Denver manufacturer to the *News* is in harmony with that lately made by Americau Minister Grey, who about a month ago returned from the City of Mexico to his home in Indianapolis. Mr. Grey declared that capital was eagerly seeking investment in Mexico, that manufacturing industries and railways were rapidly increasing, and that the country was making extraordinary progress and enjoying extraordinary prosperity.

PROFESSOR HEILPRIN says in the *New Science Review* that, however tempting other explanations may appear, scientists have gradually settled down to the conviction, made inevitable by a practical demonstration, that the guiding power of ocean currents is resident in the non-periodic winds, or such as blow constantly from definite quarters.

MARINE INSURANCE was practiced in Rome B. C. 45. It was very general in Europe before the discovery of America, and it is altogether probable that the ships of Columbus were insured for their full value.

Some Commendatory Notices.

The following from our friends of the interior illustrates the feeliug with which this paper is received in all mining communities. Space precludes the reproduction of more than one-tenth of such comments which, though not republished, are uone the less appreciated:

Brighter Than Ever.

The MINING AND SCIENTIFIC PRESS, published at San Francisco, has just ended thirty-four years of usefulness, and is brighter than ever. This journal has filled a field, and filled it so well, that it now ranks above any of its kind in the United States. Being published in the very midst of the mining industry, it has advantages which others do not possess. We wish the publishers continued prosperity.—Auburn Republican.

Valuable Information.

The MINING AND SCIENTIFIC PRESS has entered upon its thirty-fifth year with indications of increased prosperity. It devotes much space to the mining industry of the Pacific coast, laying before its readers valuable information relative thereto. It should receive hearty support among the miners. —Plumas National Bulletin.

A Good Paper.

With the issue of December 29, 1894, the MINING AND SCIENTIFIC PRESS completed its sixty-ninth volume. While a "class" paper it has been for more than thirty years a welcome visitor in every mountain household. Abounding in matter of interest to miners, it has carefully withheld the use of its columns from the *promoter* and the *boomer*, who for many years have been a dead weight on the mining industry of the State.—Plumas Independent.

A Journalistic Success.

With 1895 the MINING AND SCIENTIFIC PRESS, of San Francisco, begins its seventieth volume and thirty-fifth year of publication. This journal is one of the most widely and favorably known on the coast, and we have yet to find the first subscriber to it who has anything but good words for it. It is one of the journalistic successes of the West, and we hope it will enjoy continued prosperity.—Inyo Register.

Reliable Information.

The MINING AND SCIENTIFIC PRESS has completed its sixty-ninth volume and is thirty-four years old. It is the oldest paper of its class in the United States, and the best paper we know of to afford reliable information concerning the mining industry of the Pacific coast. Every mining man should read it and keep up with the times.—Placerville Republican.

Money Well Spent.

Miners should take more interest in the MINING AND SCIENTIFIC PRESS, at least in this section. It has just closed the thirty-fourth year of its existence, and certainly keeps apace with the progress of the age. Go to Shepherd, or to any other news agent, and subscribe for that excellent organ of your industry, and we know you will not regret it. Its price is $3, but it will be money well spent.—Georgetown Gazette.

The Peer of Any Publication.

The MINING AND SCIENTIFIC PRESS, of San Francisco, has just entered upon a new volume that will close the thirty-fifth year of its publication. As a practical journal for miners, it is the peer of any publication in the world. It has established a reputation for accurate and reliable information, and is up to date in all informatiou concerning the mining industry. Perhaps the greatest compliment the MINING AND SCIENTIFIC PRESS has received was the notification from the United States Committee on Awards of the World's Columbian Exposition that the paper had received an award "for its general excellence and reliability, and the fullness and accuracy of its reports."—Colfax Sentinel.

MR. THWAITE, the gas engineer, proposes to use blast furnace gases as a source of power. He points out that whatever experiments or proposals may have been previously made in this direction, they could hardly have been on all-fours with his present scheme, which aims at the direct transformation of the heat of the gases into power iu the immediate vicinity of the blast furnaces, and by means of the direct combination of gases in internal combustion engines of the largest powers available at present—up to 650-horse power—he proposes to convert this power into an electrical form of energy, at high pressures, for distribution to any works or electric light installations within a twenty-mile radius of the blast furnace.

AT the annual meeting of the stockholders of the Utah Con. Mining Co. on the 30th ult., 87,725 shares were represented and the following officers were elected to serve for the ensuing year: H. B. Havens, president; George R. Wells, H. Zadig, E. B. Holmes and A. S. Wollberg, directors. A. W. Havens was re-elected secretary and D. B. Lyman superintendent. The secretary's financial report shows a credit of $2612.

THE Colorado Fuel and Iron Company, Pueblo, Colo., the only producers and manufacturers of iron and steel in Colorado, turned out the following products during the year 1894: Pig iron, 70,961 tons; spiegel, 3,923 tons; castings, 3,109 tons; steel rails, 66,619 tons; spikes, 846 tons; merchant iron, 6,678 tons; steel angle bars, 844 tons; iron ore smelted, 156,997 tons.

ACCORDING to the *Gas World* the intrinsic brilliancy per uuit of area of the filament of an incandescent lamp is 133 times greater than that of the gaseous rival which has appropriated the first half of its name. It seems probable that in this estimate the meshes of the gauze in the latter lamp have been taken as if solid.

MR. FLOOD leaves this evening for a month's trip to New York, where he is to meet Mr. Mackay, on business, who is unable to come to this city.

LOCAL MINING COMPANIES disbursed $99,700 dividends in Jan., '94, and $180,250 in Jan., '95.

The Mineral Hydrocarbons.

Their History, Geography, Geology, Physical and Chemical Properties and Uses.

NUMBER XX.

Written for the MINING AND SCIENTIFIC PRESS and copyrighted 1891, by Henry G. Hanks, F. G. S.

1867.—In this year Professor Silliman wrote his celebrated paper on California petroleum, which called forth so much comment. It was published in *Silliman's Journal*, April 1, 1867, previous to its being read before the California Academy of Sciences, April 1, 1867, for which reason it was not published in the proceedings of that society.

The conclusion of this paper was published in the MINING AND SCIENTIFIC PRESS, vol. 14, fol. 215.

Oil operations ceased in Humboldt county in most cases. The Irwin Davis Company, by means of a portable engine, sank 626 feet, and the Union Mattole Company at 390 feet obtained thirty gallons of oil per day.

Lyon and Jenkins returned to the claims they had abandoned ten years before. Jenkins went to Sespe and Piru; Lyon remained at Pico. Lyon's Station was named for him. He died in 1883.

The "Fargo" well, sunk in Moody gulch to a depth of 400 feet, yielded one barrel of oil per day, and from a well at Griswold's place, two miles from Lexington, 500 feet deep, oil and salt water were obtained.

In a well in Colusa county, the water was seen to rise like the tide at 3 P. M. and 6 A. M. At Antelope valley, eighteen miles north of Oil Center, in the same county, there was a salt water pond, and salt water was found in wells sunk for oil. At this time, eight oil wells had been put down in Colusa county.

On January 28th, twelve barrels of crude oil were shipped from Pico canyon, Los Angeles county.

Among the mineral specimens sent to the Paris Exposition of 1867 from California was petroleum from Mattole and Joel's Flat, Humboldt county; Noble's springs, Santa Barbara county; Wiley's springs, Pico canyon; and Hughes' springs, Los Angeles county; Hayward & Coleman's and Stanford Brothers' claims, Sulphur mountain, Ventura county; from Canada Larga and Charles Stott's claim, Santa Barbara county; from Santa Cruz county; and from Bear creek, Colusa county.

Experiments made at Corral Hollow, San Joaquin county, to distill coal oil from shale were not a success.

Previous to 1867 nearly all the California asphaltum in the State was mined in Los Angeles and Santa Barbara counties. The best market was San Francisco, where the price was from $15 to $20 per ton.

1868.—In 1868 Hayward & Coleman, of San Francisco, advertised "superior lubricating oil, manufactured from California petroleum."

Mr. Davis leased Wiley springs, in the San Fernando mountains, three miles east of Pico canyon. He collected all the oil he could from the surface and sent it to the Metropolitan Gas Works in San Francisco; this was continued for about one year. This company's office was at that time at 810 Montgomery street.

1869.—An extensive petroleum business was conducted by the San Buenaventura Manufacturing and Mining Company, incorporated with a capital of $2,500,000. This company owned all the known oil springs in Santa Barbara county, except the Ojai wells, some distance inland. Several experimental refineries were discontinued. A number of establishments began to use petroleum for fuel.

The first important work was done at Pico canyon by Mr. Hughes, who put down a spring pole well named "The Pico."

1871.—Petroleum was discovered on Augmentation rancho, Soquel, Santa Clara county, and in Livermore valley, Alameda county; the former discovery was by a party of hunters, who found the water nauseating from the presence of coal oil. The Livermore discovery caused considerable excitement. At the depth of fifty-five feet, in a well being put down, gas ignited at the flame of a candle and a constant roaring sound was heard at the bottom of the well. The blue mud taken out smelled of oil and sulphur.

James P. Sargent owned an extensive area on the Juristo rancho, about four miles from Gilroy; the beds of brea covered about twenty acres. During this year they produced 500 tons of asphaltum.

1872.—Charles Stott again worked at Sulphur mountain, Ventura county, with better success. One hundred barrels of oil from Pico canyon, San Fernando district, Los Angeles county, were shipped to San Francisco for an experiment in refining.

1873.—The San Fernando district, lying thirty-five miles from Los Angeles, and thirteen miles from the mission of San Fernando, had two tunnels driven into the hills, one 70 and the other 100 feet long, from which oil flowed in a continual stream. It was conducted in iron pipes to large tanks. Oil was also dipped in buckets from superficial springs.

It was proposed to build a refinery at Los Angeles, and the following estimate of the cost of refining was published:

Cost of oil at wells or depot—cents	15.0
Hauling	2.5
Refining	2.5
Packages	3.0
Sundries	1.0
Total cost	24.0
Market value	40.0
Profit	16.0

The Star Oil Company built their first still in San Francisco, and shipped it to Los Angeles. The refinery was located at Lyons' station, one mile from Newhall. The works were under the superintendence of William B. Smith, refiner. This was the foundation of the refinery near Pico. Wood was used as fuel; there was a diversity of opinion as to the true nature of the oil, and the proper way to refine it; no satisfactory results were obtained, and in 1876 the works were sold to Scott and Baker, who also failed to make them pay. Mr. Shoemaker succeeded them, but could not make sufficient oil to be profitable. Mr. A. J. Scott then took the refinery and met with fair success.

1874.—Messrs. Temple, Moore and Pico worked in Pico canyon, Los Angeles county. The oil they obtained was sent to the refinery at Lyons' station. At this time there was considerable activity in the production of petroleum at Sulphur Mountain, Ventura country. Hayward's claim produced ten barrels daily of 32° gravity oil; Stanford's, six barrels daily; the Santa Paula Oil Company, ten barrels daily; the San Fernando company, near Camulos, about ten barrels daily. All this oil was obtained from natural flows. Two hundred barrels per month were used by the Central Pacific railroad for lubricating purposes, but there was but little other demand for the crude oil. There were also some new oil springs discovered in Sespe cañon. A deposit of asphaltum was discovered in San Luis Obispo county, on land owned by Steele Bros., and a contract was made to haul fifty tons to landing to be shipped to San Francisco.

The Chandler Oil Mining Company of Los Angeles was incorporated in February, of which George Caffey was president, and C. H. Howard secretary. B. Chandler was superintendent.

The company's wells were at Petrolia, on section 5, township 3 south; and range 9 west. The company commenced operations on section 1, range 10 west, and obtained oil at a depth of from 100 to 300 feet. The oil had a density of from 15° to 30° Beaume. One well produced 150 barrels, which sold for from $4.50 to $12 per barrel. Mr. Chandler informed me that within two years 500 barrels had been produced at Petrolia, which I visited in May, 1884. Two wells were being sunk. No. 1 was down 290 feet, and No. 2 240 feet. From No. 1 quite a quantity of black tar oil (maltha) had been pumped. A tank holding from seven to ten barrels was standing full. Common brea, which contained what seemed to be jonite, was burned under the boiler and was the only fuel used. (The presence of jonite was also observed at Sargent's, Santa Clara county.) The wells at Petrolia are on small foothill elevations above Anaheim; the direction or trend of the hills is about east by south. A small creek runs down, south by west, to the plains; on both of which brea has flowed and formed terraces as at Sargent's, and the "black tar" is similar. Of the brea there are a number of varieties—some cellular, like volcanic scoria, and mixed with sand; several grades of maltha, and some brown and light-colored bitumens resembling jonite. In several directions from the oil wells might be seen extensive patches of crude brea which had flowed from the hillsides. Mr. J. W. Snow's well was about a mile from Petrolia; it was 550 feet deep, but unfortunately for the owner it was a dry hole. This well was at first a square shaft 44 feet deep, from the bottom of which a six-inch well was sunk through the soft sandstone. At 250 feet and for 150 feet lower, sandstone was pierced. The sand was like that in the brea.

1875.—The estimated sum total of crude oil produced in the State up to date was 175,000 barrels.

1876.—During this year the California Star Oil Company of Los Angeles was engaged in sinking wells in Pico canyon, Los Angeles county; the yield of the district was forty barrels per day. The State production of oil for the year was 12,000 barrels, making the total yield to date 187,000 barrels.

1877.—The California Star Oil Company, under management of J. A. Scott, produced twenty barrels of refined oil at the Pico refinery. The Ventura wells were pumping eighty barrels daily; those of Pico canyon from forty to fifty. For the first time steam machinery was used in sinking wells at this locality.

Thirteen thousand barrels of crude oil were produced in California in 1877, making the total from commencement 200,000 barrels.

The Columbia well at Buena Vista, Kern county, was drilled by Mr. Meyers. At 300 feet the bit penetrated a cavity of oil and gas, which raised the tools 120 feet and entangled them with the rope. After this accident the well was abandoned.

Charles N. Felton and P. C. McPherson commenced work in Moody gulch, in the Santa Cruz mountains, on the old Boyer well. At 700 feet a rush of gas and oil occurred, which rose 100 feet above the mouth of the well, and 100 barrels of oil were said to have been lost. For some time after, sixty barrels of oil having a gravity of 46° were pumped from this well. The oil was sent to the refinery near Newhall, Los Angeles county.

1878.—In September of this year, in a communication to the MINING AND SCIENTIFIC PRESS, Mr. Edward Madden, an oil expert, stated that the oil of Ventura county was inferior to that of Pennsylvania as an illuminator, but superior as a lubricator. In the same paper he gave the production of the Star Oil Works at 150 barrels per day and the yearly consumption of oil in the State at 3,500,000 gallons, valued at $1,000,000. His opinion based on surface indications was that the southern portion of Los Angeles county was full of oil. The total production for the year was 15,227 barrels; total production to date, 215,227 barrels.

1879.—On the 10th of September the Pacific Coast Oil Company of San Francisco was incorporated. There were five wells at Pico from 200 to 600 feet deep, eight in Ventura county on ex-Mission lands, all yielding oil by pumping, and one well at Sespe, 1500 feet deep, yielding 100 barrels of oil per day. A refinery at San Buenaventura caught fire and was blown up. The yield of oil in the State for the year was 19,858 barrels and the total to date 253,085 barrels.

220 MARKET ST., N. E. Corner Front (Up Stairs), SAN FRANCISCO. Experimental machinery and all kinds of models. Tin and brasswork. All communications strictly confidential.

RUPTURE!

It has been considered by the medical profession that hernia—commonly called rupture—was incurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But DR. J. C. ANTHONY, of 86 and 87 CHRONICLE BUILDING, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patient no pain, and those living near enough do not lose any time only while in his office once or twice weekly. He guarantees every case he treats, and does not ask a man for a dollar unless he cures him, so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medical College, of New York City.

PLACER
Amalgamators,
Dredgers,
Shovels.

Complete "Lancaster" Gold Amalgamating, Concentrating and Hoisting plants furnished for treating large quantities of low grade placer ground at a small cost with minimum supply of water or compressed air.

Highest possible Gold yield insured.

Outfits include "Lancaster" 1895 Land or River Dredges, Grapples, Scoops, Steam Shovels and Cableways of the most approved construction. Success guaranteed. Capacity, one hundred tons hourly and upward, if required.

Crushing, Pulverizing, Concentrating and other machinery also built.

Investigation solicited.

JAMES H. LANCASTER, Patentee,
37 CORTLANDT ST., NEW YORK.

HEALD'S
Business College,
24 Post Street, - San Francisco.
FOR SEVENTY-FIVE DOLLARS
This College instructs in Shorthand, Type-Writing Bookkeeping, Telegraphy, Penmanship, Drawing, all the English branches, and everything pertaining to business, for full six months. We have sixteen teachers and give individual instruction to all our pupils.
A Department of Electrical Engineering
Has been established under a thoroughly qualified instructor. The course is thoroughly practical. Send for Circular. C. S. HALEY, Sec.

LIGHTNING LARGEST WELL MACHINERY Works.
All kinds of tools. Fortune for the driller by using our Adamantine process; can take a core. Perfected Economical Artesian Pumping Rigs to work by Steam, Air, etc. Let us help you. THE AMERICAN WELL WORKS, Aurora, Ill.; Chicago, Ill.; Dallas, Tex.

Scientific Progress.

Economy Through Thermal Storage.

Not only does the modern steam-power plant extract a mere fraction of the latent euergy stored in the coal cousumed, but that fractiou is often subject to serious diminution where the work to be performed varies from hour to hour. It is a well-known fact that the proportion of fuel required to each horse power used is greater in such a case than when the work coutinues at an eveu rate through the whole twenty-four hours, as, for instance, on an oceau steamship. In electric light and railway stations the "load" is very heavy during part of the day, and very light during the rest of it. It has been computed by Prof. Forbes that even with the most careful management the extra fuel burned in a lighting station amounts to forty-three per cent of the quantity that would otherwise be used; and with less care the excess would be still greater.

How to avoid this waste is a problem for which experts have found various partial solutions. One plau that has recently been adopted by progressive managers is to run the engine at a proper average speed right through the day, to store most of the electrical output in accumulators during the comparatively idle hours, aud then to draw on these as well as the dynamo when the load is at its maximum. But such a system adds largely to the original cost of the outfit, and, it is alleged, wastes at least twenty per cent of the stored euergy. It seems probable, therefore, that what is called the "thermal storage" idea, which has yielded excellent results abroad, will receive increased attention.

A plan adopted with a satisfactory degree of success maiutains a uniform fuel consumption, and when the load is light conveys the surplus heat to water tauks, which are suitably connected with the boiler, and whose capacity has been very carefully adapted to the requirements of the station. Iu these tauks the temperature is permitted to rise considerably above what would be the boiling poiut in open air, but as the water is kept under high pressure aud no surface is exposed, no steam actually forms, except in the boiler. This storage goes on until, when the hour for the maximum load has arrived, the temperature is about 406° Fahr., say. This is equivalent to a pressure of 250 pounds to the square inch. It is desirable, let it be assumed, to run the engines during the period of heavy work at 130 pouuds pressure, to produce which, normally, a temperature of 347° would be necessary. So great is the quantity of heat actually stored in the tanks that the boiler will make steam fast enough to keep the pressure above this minimum until the time comes for taking off the load. Then, of course, the accumulation of energy is resumed, and proceeds gradually as before.

It will be seen that the boiler proper ueed have a capacity only suited to the mean of the whole day's requirements, and not, as in other plants, equal to the utmost demands at the very busiest hour. Hence it has been found that the cost of the plant, including ten or a dozen tauks with the proper fittings, may be considerably less than that of the type now iu common use.

The "heat storage" plan here described is au improvement on the steam-storage system, which has been tried with good results, but which requires larger and more tanks. There is also iu contemplation a combination of the two. To install it, however, costs more than the simple heat-storage outfit.

THE French Societe Technique offers the following prizes to persons of any nationality: £409 for a markedly better incandesceut gas lamp, to be sent in before April 1, 1895, the council to decide whether the time may not be extended to May 1, 1896; £320 in various prizes for essays on any subject affecting the gas iudustry, particularly on mechanical handling of coal, coke, etc., ou water, gas or revivificatiou, or on the substitution of hydrocarbous for cannel; £80 between those who have made the greatest progress in apparatus for making or using of gas. Papers to be in French, and unpublished; motto, with uame iu envelope, and a declaratiou inside that the paper is unpublished, aud that the author will not publish otherwise for a year. To be sent to the Societe, 65 Rue Provence, Paris, by the eud of April next. Also prizes of £10 to the authors of the best papers at the aunual meeting, provided iu this case that they are members of the Societe.

The Electric Incandescent Lamp.

The best and, in fact, the only really efficient incandescent electric lamp of to-day, says J. H. Cunz, in *Cassier's Magazine*, is characterized by a continuous glass chamber, from which the air has been exhausted and in which is the light-giving carbon filament, supplied with current by platinum wires, sealed in the neck of the glass bulb. This seems a simple enough contrivance, but the preparation of the materials and the putting of them together involves the greatest care, and the presest high state of the art has been attained only after many years of ceaseless labor and patient effort.

The carbon filament has probably caused more work and worry than all the rest of the lamp put together. It is the essential part. Uutil lately the raw material for its preparation was bamboo, which was cut into thin strips and carbonized, but now some artificial compound of carbon is used, the exact nature of which is kept secret. This substauce is cut into thin strips, and is carbonized by heating in a suitable furnace. These carbonized filaments are of various lengths and thicknesses, some having a diameter of only five-thousandths of an inch, and are bent into different shapes, the one most favored at present being the spiral. At the largest lamp works in the United States all the sixteen-candle power high voltage lamps—the most common size there—are now made with spiral filaments, as well as all lamps above sixteen-candle power. The more familiar "horse-shoe" and "hairpin" filaments, however, still have a place in the art, particularly in the smaller-sized lamps. Sixteen, twenty, twenty-four and thirty-two-candle power fifty-volt lamps are still made in plain loops, and probably always will be.

A New Electric Process.

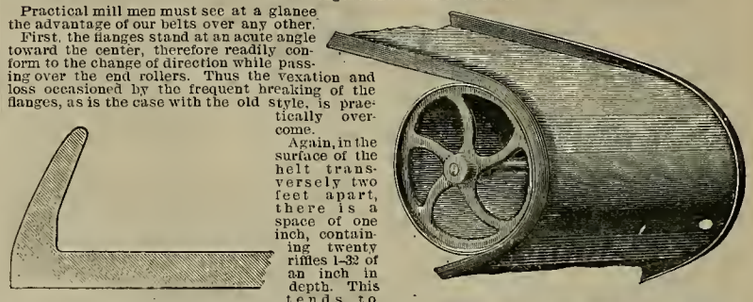
One of the most remarkable of recent inventions is a process for making caustic potash aud soda out of brine. These substances are utilized in the manufacture of soap, glass and paper. Hitherto they have been obtained by costly methods, the production of them being a very important industry in Great Britaiu. Nearly all of the soda and caustic potash used in this country is imported from Englaud, amouuting to millions of dollars' worth annually.

It has been discovered that these alkalies may be obtained by decomposing brine by means of electricity. The brine is got from salt wells Sea water would serve, but it is not as good for the purpose because it contains much less salt. Already the manufacture of caustic potash and soda has been begun in Michigan and elsewhere in the United States. The matter is exciting great attention here and abroad, and all the leading chemists of the world are working at it. The inventor of this process is a Belgiau uamed Hermite.

In Europe they are uudertakiug to disinfect cities by the use of this process. All that is ueeded is to run wires from a dynamo iuto a vessel of sea water, and the latter yields a product which is the same thing as what is commonly known as "bleachiug soda." The stuff is so cheaply obtained that it is being used to purify sewers aud is poured iuto gutters. Eventually it will be extensively employed in the sprinkling of streets. By this means of wholesale disinfection, which signifies the destruction of disease-produciug germs, cities will be rendered much more healthy in the future.

Blasdel Improved Concentrating Belt.

We keep in stock belts suitable for the Frue, Triumph, Johnston and Tullock machines, and make all lengths and widths to order.



Practical mill men must see at a glance the advantage of our belts over any other. First, the flanges stand at an acute angle toward the center, therefore readily conform to the change of direction while passing over the end rollers. Thus the vexation and loss occasioned by the frequent breaking of the flanges, as is the case with the old style, is practically overcome.

Again, in the surface of the belt transversely two feet apart, there is a space of one inch, containing twenty riffles 1-32 of an inch in depth. This tends to equalize the pulp and prevents it from banking on the edges, or forming channels. This riffle saves fine sulphurets and quicksilver that would escape with the tailings from a belt with an entirely smooth surface.

PATENT SOLICITORS.

ESTABLISHED 1863

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S.F.

Mechanical Progress.

Value of Mechanical Skill.

A subject that appears well worthy the attention of the apprentice and young mechanic is the actual difference between the value of thoroughly skilled and competent labor, and half-skilled and incompetent labor. At first thought it would seem that if one mechanic were capable of doing two-thirds as much work as another, in order to do exact justice to all parties he should receive two-thirds as much wages. In point of fact, however, there would be injustice in such arrangement. In order to divest the matter of the wages aspect, let us suppose that two men enter into partnership, and that the better workman can perform labor representing $1500 per year, and the poorer one two-thirds as much, or $1000 per year. Suppose, further, that they find the interest on the plant required to conduct the business, sinking fund and incidental expenses, to be $1200. Since it is evident that each will occupy the same amount of room, and that each will require the same tools with which to work, it is evident that the $1200 in the way of expenses should be equally assessed, and that the amount to which they would be equitably entitled in the way of wages would be $900 and $400 respectively. In other words, the one who does one-third more work than the other is, in strict justice, entitled to two and one-fourth times as much as the first. Now, the matter would in no sense be changed, if, instead of working for themselves, they work for a third party. It is a consideration of this fact that leads far-sighted employers, especially in a business that calls for large expenditure in the way of tools, etc., to look for very competent men. It is always apparent that the mechanic who has given the greatest amount of energy to thoroughly comprehend and manage his business is always the one who has work and good wages without much reference to the times. He who by diligence fits himself to do more and better work than another will find himself much better paid, and in a greater degree than would be indicated by the extent of his superiority. In this there is nothing but exact justice to all parties. There are, to-day, greater inducements for the young mechanic to improve and perfect himself in his trade than ever before. The absolute value of skill, from a business point of view, is fairly appreciated by those who have the hiring of it.

Electric Power in Manufacturing Establishments.

There have been many cases of the use of electric motors to drive lines of shafting or isolated parts of plants to prove conclusively the remarkable increased efficiency obtained, especially where the conveyance of steam for a long distance was necessary. This has led to a more thorough study of the amount of power absorbed by the line shafting and countershafts. W. E. Hall, in *Cassier's Magazine*, says the minimum loss that can be looked for—and this is obtained only in exceptional cases requiring constant vigilance—is twenty-five per cent of the total power developed, and more frequently runs as high as sixty-five to seventy per cent. A safe average would be from forty to fifty per cent, although the actual loss must be determined for each and every case. With the use of electric motors, when properly designed and proportioned for the work, as, indeed, is as necessary in electrical work as with any other problem of mechanics if the best results are desired, this percentage of loss can be materially reduced. An inefficient result must be expected with bad electric engineering just as with a poorly arranged case of millwrighting; but, the electrical proportions being once obtained, there will, within reasonable limits, be no decrease in efficiency from deterioration.

The advent of electricity for such purposes seems to have enabled managers to realize more fully than ever before the loss accompanying what was heretofore generally accepted as the most efficient method of furnishing power to the individual machines of a plant. The use of electric motors in the place of shafting and on isolated machines where the motors are belted direct to the isolated shafts or to the machines has been sufficiently extended to render the verification of the results obtained unnecessary. It is no exception to find a reduction of fifty per cent of the power consumed. This is not due entirely to the saving of loss through friction, but also to the advantage gained by the intermittent action of machinery of every kind. Tests show that where the motor drive has been substituted, the machines are in operation but little more than one-half the time, or, more correctly stated, the power required is only about one-half the total average power of the machines when doing work. As remarkable as these results may seem, sufficient data are on record to prove their correctness.

In the forced draught trials of modern high-speed vessels and the terrific strains endured by the several members of the engines, the extraordinary integrity of the materials composing them is remarkable. This is in all cases machinery steel, and its endurance under the work done is sufficiently remarkable to warrant comment. Modern machinery of greater or less carbonization bears a certain stress in the testing machine, but this stress is in no degree comparable with the work demanded of steel under the crucial test of a forced draught trial. Then it is yank, jerk, and jar without end, each strain alternating, even combining with the other, and the whole kept up for hours at the very highest tension steam is able to put upon it. It almost seems at times as though upon the reciprocating parts that the heads would be jerked off of the bolts, and that no material could stand the usage that modern steel gets. With all this, the details are not heavy and clumsy, they are the reverse of this, being even lighter than they were many years ago. The fact of the matter is, that, in addition to excellence of material in the beginning, the systems of inspection, and thorough working that steel receives in modern forges, leave no flaw undetected. Breakdowns are very rare indeed, in comparison with the number of engines in use, which fact justifies our conclusions. — The Engineer.

It is remarkable, says the *Iron and Coal Trades Review*, how very many of the greatest inventions and discoveries of modern times have been achieved by men who were not themselves trained to the business or profession in which they acquired distinction. Neither Bessemer nor Siemens was trained as a metallurgist, and yet they have been proclaimed as the most epoch-making inventors in the history of the iron trade. Sir William Armstrong was not trained as an engineer, but as a solicitor, and yet he has revolutionized the art of gunnery and the manufacture of hydraulics. And so with many other modern instances. The so-called practical men are too often incapable of looking all round a subject, and are so wedded to usage and established rules as to look with serious disfavor upon any really novel ideas, however meritorious.

Half-a-dozen years ago it was imagined that machines were already invented for making screws at the cheapest conceivable rate. Lately, however, a much less costly process has been devised. Instead of cutting out the thread of each screw, as used to be done, two dies are used to press the metal into shape. Every time the dies come together a perfect screw is made, and the rapidity of production is astonishing.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

GENERAL MINING ITEMS.—*Record:* The repairing of the Zeile shaft moves slowly, owing to the flow of water. Two buckets are constantly hoisting water. These take out nearly 200,000 gallons every twenty-four hours, and with this immense output the water is only kept at a standstill. The water is at the 900 level, with nearly 250 feet of sump.

At the Anita they are busy with the steam hoisting works. All the machinery is in place. The shaft, 100 feet deep, is full of water to within thirty feet of the surface.

At the Wildman mine the thirty stamps are busy night and day to their full capacity on fair-paying rock. On the 1300-foot level the south drift is now in 435 feet from the shaft. The size of the ledge and its quality remain the same as at the last writing. On the 1220-foot level the head of the south drift is now 225 feet from the shaft, with equally as good a showing as at the same distance from the incline on the lower level. The mine never looked better in its many years of active life than at the present time. The ledge is large, and the ore chute on the 1300 level has been run through a distance of 400 feet lengthwise of the ledge, with the end of it not yet in sight.

LIVELY NEXT SPRING.—*Republican:* Some old mines east of Sutter Creek, Amador county, are being reopened. Late reports from Plymouth and vicinity are of an encouraging character. The coming spring will see a small army of prospectors searching mountain-side and ravine for new mines. The boom that has lately struck Amador has not as yet added very materially to the output of '94, as a large amount of preparatory work has been necessary—pumping out old workings, rebuilding hoists, erecting mills, etc.; but the year of '95 should see a substantial evidence of the activity that marked the close of 1894.

The South Spring Hill mill will soon be started up on rock from the Median mine, which adjoins on the east. This property gives every indication of proving a good mine. A test crushing was made some time ago, and the yield was highly encouraging to the owners, although we are not in a position to state the exact amount per ton. The company has secured a bond of the El Dorado claim, which joins the Median on the south.

At the Kruger mine, in Hunt's gulch, they have been engaged on contract in sinking a shaft. They reached a depth of 120 feet, when the flow of water became unmanageable with the appliances at hand. About two weeks ago the shaft caved to within thirty feet of the surface, rendering it useless. It would cost more to fix it up than to sink a new shaft.

Calaveras.

MAKING A TEST RUN.—*Chronicle:* C. A. Rice has been making a test run of twelve tons of ore at the Tripp mill, on the Mokelumne river. The ore was taken from an old mine on the Peek ranch, about a mile and a half from town, and which has been bonded by the Linderaxa Mining Company. The mine was worked by Mexicans forty years ago, they having run an arrastra on the mine for two years. There are two shafts on the mine—one 50 and one 75 feet deep—and there is also a tunnel in 50 feet. A contract has been let to extend the tunnel 25 feet, work on which is now being prosecuted.

El Dorado.

UNTER DER LINDEN.—*Democrat:* When we mentioned the fact that the cleanup of twelve pounds and five ounces of gold from a run of five days, at the Lindeu, during the fore part of the month, was only a small draft on an inexhaustible deposit, we were not mistaken in our predictions. The last run of five days, made last week, coppers all previous runs by several pounds—the exact weight being twenty pounds. This is encouraging, not alone to the company, but to all of our citizens who have the mining fever in its most virulent form.

Mariposa.

Gazette: W. S. Chapman has purchased an interest in the Vanderhilt mine, and under his direction a new impetus will be given to the working of this mine. During the winter only a few men have been employed by Mr. Beebo, but as soon as settled weather comes an increased force will he put in the mine and mill. The mill is to be moved from its present location and ten more stamps added. The Vanderhilt is a good mine and can he made to pay under proper management.

Nevada.

RICH LEDGE UNCOVERED.—A rich strike has been made in the Hecla mine at Grass Valley. The quartz vein is narrow, from eight to ten inches, but it is expected to widen as it increases in depth, and the ore is full of free gold. Considerable rock has been extracted, and arrangements are being made to have it crushed at the Omaha mill.

San Diego.

The old Escondido mine is at present being shut down, but will soon start up again. An incline has been sunk on the vein to a short distance below water level, 80 feet. No drifting or stoping has been done below water. Some ore has been extracted and worked in a crude mill on the mine. About one-half mile northeast from this mine, on the same mineral belt, is the Oro Fino mine. An incline has been sunk on the vein to a depth of 75 feet, to water level, where a drift has been run southwest a distance of 15 feet, exposing a body of ore 20 inches in thickness in the backs. At a depth of 35 feet a drift has been run southwest along the vein 130 feet. Some stoping has been done above this level, and a quantity of fair grade ore has been extracted and milled. A Tustin pulverizer and gasoline engine are located a quarter of a mile below the mine, where the milling is done.

San Bernardino.

Our Vanderhilt correspondent writes: Shipments of ore and bullion from the Gold Bronze mine up to date amount to $50,000. The main shaft is now 287 feet deep, showing better grade of ore than at any other depth. The ten-stamp mill is running daily. Twenty-five men are employed at this mine.

At Boomerang mine, owned by the Brick Consolidated Mining and Milling Co., main shaft is 535 feet deep, showing good body of ore, sufficient water is hoisted from this shaft to run ten-stamp mill about twenty-two days a month. About thirty-five men are employed by this company.

Siskiyou.

GENERAL MINING NOTES.—*Journal:* Austin & Co., of the Greenhorn blue gravel mine, are putting up more boxes, to put more men at work. The great amount of snow on the mountains will keep up the water supply for successful operations full-handed until late in the summer, or probably until winter comes again.

The Schroeder quartz mine at Deadwood mountain is still paying well, with a large force taking out quartz to keep the mill running steadily, notwithstanding the deep snow in the vicinity. By keeping the snow shoveled out between the tunnels and mill, there is no difficulty in operating the mine successfully during the entire winter.

Michael J. Loftus and brother, prospecting for quartz in the Shasta valley divide east of Scott valley, have found a good-paying quartz ledge seven miles from Fort Jones, east of Mount creek. The ledge is eighteen inches thick and prospects $17.50 per ton, besides containing a large percentage of silver. There is considerable snow at the mine at present, but it does not interfere with opening the ledge for development.

The new quartz mill the Jillson company is putting in to crush blue gravel, near Henley, is a ten-stamp one, double-discharge battery. The building which will inclose it is 24x84, and the height from the lower grade to the peak of the roof is fifty-eight feet. The wheel to furnish the power for the mill will he a six-foot one, under 300-foot pressure.

Hossick & Brown have commenced making a ditch on Humbug creek, to work their claim next month when the snow melts sufficiently, and expect to realize good pay, as their claim prospects well.

There need not he any complaint among the miners this winter about lack of water supply for any kind of mining, as there is an abundance to start the hydraulic giants and quartz mills everywhere. The river miners, of course, are driven out, but that is expected every winter when the heavy storms occur.

The Black Jack Co. will soon put up a quartz mill for crushing the blue gravel cement taken out of the claim at Cottonwood, and Jillson & Co. are also getting ready to put up their mill, the machinery for which has arrived at the depot in Hornbrook.

Tuolumne.

Independent: The Seminole mine, near Soulshyville, discharged fourteen men lately. Parties interested are here from New York, and will return and report. It is said that the plan of working the mine will be changed; that a tunnel will be run from the north fork of the Tuolumne river, and that a large mill will he erected at or near that point, but nothing can yet he confidently stated.

NEVADA.

J. Balzar and W. S. Dickerson have taken a new lease of the Pamlico mine, near Hawthorne, for 1895. Their lease includes the entire mine, but they will probably sublet the south end. Two and a half tons of ore from this mine, worked by an arrastra, yielded seventy-two ounces of gold, or $1224 at $17 per ounce. In one year two lessees of this mine, working themselves, have taken out $14,000 in gold.

ON THE COMSTOCK.—Dan De Quille: The various companies working mines on the Comstock lode will get through the winter in fairly good shape. The bullion now produced is mostly gold. There are several mines now producing milling ore. Much of this is of low grade, but its extraction and milling gives employment to men who would otherwise be idle. Of the productive mines the Con. Cal & Virginia is still in the lead, yielding an average of 350 tons of ore a week that pays over $60 a ton. In this mine marked improvement has been shown during the past week on the 1650 level. At this point a drift was run south, and after passing through low-grade material for a distance of 38 feet it cut into a body of ore that assays $30 a ton. This shows well for ore to the southward, both above and below, at that distance from the main winze.

The Savage has sent to the Nevada mill 270 tons of ore assaying $33.85 a ton. The streak of gold ore found on the 975 level of the Hale & Norcross mine continues, and during the week has yielded seven carloads of ore assaying $93.50 a ton. The Justice has yielded 153 tons, yielding $16.81 a ton, over half gold; Alta, 52 tons, worth $22.44 a ton. The Challar sent to the Nevada mill 235 tons of ore, assaying $30.50 a ton. The Potosi and Occidental have also yielded small amounts of pay ore.

TO BE REOPENED.—Genoa *Courier:* James Titus, who resided in Genoa in early days and went to Arizona, returned a short time ago with the intention of working a mine fifteen miles northwest of Mineral Hill, in the Pine Nut range of mountains. It was first located in 1859 and patented in 1867. The ore assayed $28 per ton in gold and silver. Mr. Titus had twenty-five tons worked in early days, but on account of the high rates charged for milling ore and working the mine it did not pay. He thinks now it can he made to pay a handsome profit. He says the ledge is twelve feet wide. There is a 200-foot tunnel that was run in early days, but it will require a large amount of work and no small amount of expense to open it again, as it is caved in for 100 feet or more, and timbers are rotted off. As soon as the weather will permit, Mr. Titus intends starting up work, and will build a dwelling near the mine. He says there are several hundred tons of rich ore on the dump, and that he will have it worked at Dayton or Silver City. He says he has been offered $25,000 for the property, and that it is worth more.

ARIZONA.

BRADSHAW DISTRICT.—The Reliable and Gladiator mills are running night and day on good ore from their respective mines. There are about twenty men working in the Gladiator and ten at the Reliable.

Work has started on the Peck mine. A. Falco has men at work cleaning out old tunnels, drifts and cuts. A contract for 150 cords of wood for the hoist has been let out, the water in the shaft, now about 500 feet deep, will be pumped out and the shaft and tunnels retimbered if necessary, then the old crosscut from the bottom of the shaft to the Occident, a parallel lead, will he pushed ahead. The Peck mine is the richest silver mine in Yavapai county, having produced over one million dollars in former years.

BRITISH COLUMBIA.

SLOCAN SHIPMENTS.—Slocan shipments in 1894 are valued at $564,800. The total amount of shipments reported is 4718 tons. Of this, 2152 tons went over the Nakusp & Slocan and Canadian Pacific. The total valuation of this ore is placed at $216,245, or about $100 per ton. Most of it came from the Alpha and the Slocan Star, though the Mountain Chief, Idaho, Reco and some of the Noble Five properties made shipments.

On the other side of the district, 2566 tons of ore left Kaslo during the year. The total value of this ore is placed at $348,582, or an average of $136 per ton. The average valuation of the 4718 tons shipped in both directions would he about $120. Of the Kaslo shipments the Great Falls smelters got about one-third, while Omaha took about one-quarter and Denver nearly one-fifth.

December shipments from West Kootenai are figured at $100,000. During the two weeks ending Jan. 8th, 1000 tons of ore were shipped from the Slocan district—mainly from the Idaho and Slocan Star—and the valuation of that fortnight's output is figured at $125,000.

The Hall mines at Nelson, though worked on a very limited plan, sent out 800 tons of ore, valued at $80,000. The Trail creek mines, which are just getting started, shipped about 2800 tons last year, which may he estimated at $140,000.

At Camp McKinney the Cariboo Mining Co. started up a ten-stamp mill last fall and are now shipping between $12,000 and $14,000 in gold bars every month, besides sending out concentrates. There are thirty men employed on this claim, which lies alongside the Amelia on the same vein. A ninety-foot shaft is being sunk to tap the tunnel on the Carihoo, the intention being to drift along the vein into the Amelia. The same company have purchased the lease of the Laura, a hydraulic claim, at Rock creek, fifteen miles from Camp McKinney, and will go to work on it in the spring, putting in a stronger plant.

NEW DENVER ITEMS.—The Noble Five has made another sale of 500 tons of ore to the Omaha smelter.

H. Sherau has sold a half interest in the Columbia on Trail creek for $4000.

Heavy hoisting machinery will be put in the Dardanells, and work on that claim is suspended till it is in place.

Work has stopped on the Cumberland owing to snow slides. This mine has shipped 120 tons of ore this winter.

The Government has been asked to extend the trail on Wilson creek to the dry-ore belt at the Dolly Varden group of claims.

OREGON.

Baker Co.

Democrat: The White Swan Mining & Milling Company, incorporated under the laws of Iowa, has bought the White Swan mine. A one-fourth interest in the property is retained by G. S. Tarbell, of Baker City, the discoverer and original owner of the mine, who has been superintending and conducting the property on his individual resources since the Union Mining Company was displaced.

The debts contracted by the Union Mining Company, amounting to upwards of $25,000, have been paid in full by the new company taking charge.

The transfer of the property will succeed Mr. Tarbell as manager of his own free will, and his successor will very likely he Col. A. H. Swan of Ogden, Utah, who is a stockholder in the company, and who was the promoter of the sale.

The White Swan has now a pay-roll of about $4500 per month, and as a producer of gold bullion has few equals in the Northwest.

Josephine County.

The Black Channel Mining Company are pushing development on their property; their tunnel is now about 1300 feet long. They will only run one giant this winter; they have thirteen men employed.

NEW MEXICO.

NEW SMELTER.—The American Zinc-Lead Company have recently completed a smelting plant at Ivanhoe, Grant county, where they will make a specialty of ore containing copper, but will treat all ore except heavy lead. They have secured the old Santa Rita copper mines, and several other properties containing an abundance of iron ore suitable for flux. The works are between Demipg and Silver City, on the Silver City and Northern Railroad, and are in charge of S. E. Bretherton, formerly superintendent of the American works at Leadville.

IDAHO.

The upper workings of the Gem mine are closed down, laying a number of men off. The sinking of the main shaft continues. Development on the first level continues, with enough ore coming out to keep the concentrator running twelve hours per day. The ore body uncovered at the first level is exceptionally fine, and the fact is developed that this is not the same ore body as that in the upper workings. The company is working about 60 men. The Frisco is working a full force.

MONTANA.

AT LUMP GULCH.—The Kennedy mine, located about a mile and a half west of Liverpool, now lying idle, was, a few years ago, one of the leading silver producers of the West, ranking with the old Legal Tender. About thirteen years ago the property was leased by M. E. Downs and O. R. Allen, who worked it until about two years ago, taking ore from the drifts and crosscuts above the 150-foot level.

Ore was taken out of this mine by the lessees and shipped to the Grant smelter at Denver, that was almost pure silver. Chunks of ruby ore were taken out that were worth their weight in coin. The writer was informed by an old miner who worked there at the time that ore shipped to the smelter yielded from $20,000 to $22,000 per ton.

After Downs & Allen threw up their lease, Kennedy worked the mine himself for a short time, taking out an immense sum of money. When the depreciation of silver came, Kennedy shut down the property, and it has remained idle ever since.

There are several mines in the Kennedy group, all of which are patented. On one of them a shaft was sunk 250 feet. The property is now in litigation, a mortgage on it being held by Thomas Cruse of Helena. It would be a great addition to the camp if the mine could be again put on a producing basis.

UTAH.

THE BULLION-BECK AND AJAX.—Tintic *Miner:* Samuel McIntyre, the new general manager of the Ajax Company, took charge of the property on last Saturday and immediately laid off all men employed there and ceased ore shipments. It is proposed to at once sink a shaft from the end of the tunnel level, which is in 200 feet, to a depth of fifty feet, and drift from that point. To that end a contract was let to C. S. Johnson of Eureka for sinking the shaft at the rate of $10 per foot, that being the lowest bid, and the work to commence at once. The shaft is to be 6x12 feet, and by sinking the 50 feet proposed they will be about 185 feet below the surface.

The Bullion-Beck Company has finished laying the new five-inch pipe line from the reservoir on the divide to the mill and closed up the ditch. The main portion of the mill will be up and under cover by the end of this week, and the work of placing the boilers and heavy machinery will commence at once. Work will commence on the tramway next week. Since the commencement of operations at the Eureka Hill mill no concentrates have been shipped, and it is estimated that there are on hand over 100 carloads. A few cars are now being loaded and will be shipped in a few days. Tuesday was pay day at the Beck, about $16,500 being distributed by that company.

THE plans for torpedo-boats Nos. 3, 4 and 5 have been received by the Iowa Iron Works, at Dubuque, which is preparing to bid on them. The faults in design and the placing of machinery, to which the builders attribute the mishaps attending the Ericsson's trial trips, are avoided in the plans for the new boats. Their speed will be 24½ knots, and the cost of all, including armament, is not to exceed $250,000. The Ericsson cost $113,000 without armament, and her speed requirement is twenty-four knots. Her trial trip will not be witnessed until late in March.

THE heavy seas rolling over the bar last Sunday played sad havoc with the north jetty trestle, and in a few minutes destroyed the labor of weeks. Thirty-one bents, representing 496 lineal feet of double-track trestle, with railroad iron, piling and everything, were carried away by the huge rollers. The breach was made by the sea end, leaving five lone bents standing out in the ocean, which threaten to go out also. Considerable of the wreckage has come ashore along the ocean beach and will be saved, but it will be impossible to replace the trestle work before spring.—Humboldt Times.

A SWEDISH ENGINEER proposes to do away with rifling in cannon by supplying each projectile with a gas-check to prevent any of the gas escaping past it. And then he would impart to the gun itself a rotary motion, at the instant of firing, which would give the projectile the necessary twist. The benefits thus derived, he intimates, would be reduced cost of construction and longer life.

Coast Industrial Notes.

The Victoria sealing fleet took 94,474 skins in 1894, as compared with 70,332 in 1893.

—The British Columbia salmon pack in 1894 was 494,470 cases, against 596,584 cases in 1893.

—The capacity of the Roche harbor lime works, on San Juan island, is 1500 barrels per day.

—There are twelve vessels loading at the Port Blakely, Wash., mill, and the big plant has resumed running nights.

The Sacramento and Ione Coal Company will soon go out of existence. Their mine at Angels has been worked out.

The $200,000 Astoria, Or., water bonds have been sold to Rudolph Kleybolt & Co., of Cincinnati, for 95 and accrued interest.

—A line of steamers is to be established between Victoria and Mexico. The s.s. Danube of the C. P. N. Co. will make the first voyage.

—The $5,000,000 Lake Washington Canal bonds have been floated in St. Louis, Mo., and Seattle men expect to begin work thereon by the 15th prox.

—The Chuckanut stone quarry at Fairhaven, Wash., which has furnished stone for a large number of buildings in the Pacific Northwest, has a producing capacity of 10,000 tons monthly.

—Robert Chabot, who recently purchased eighty acres of swamp at Long Beach, Wash., for the purpose of engaging in cranberry culture, has contracted for 480 acres more, with the intention of still further broadening out in the industry.

—Under the income tax law an unmarried woman with an estate worth $5000 a year will be allowed the exemption of $4000, but if she marries she will have to pay the income tax on all, which is equivalent to taxing her $80 a year for getting married.

—There is a proposition on hand to let the State printing to the lowest bidder. During the past two years the printing bills footed up $219,950.37, and a San Francisco publishing house has made an offer to do the same work for the next two years for $50,000.

—During '94 there were shipped by cargo from Tacoma, Wash., 55,063,000 feet of lumber, a decrease of 7,000,000 feet compared to '93. Of the above this city took 16,952,000 feet, San Pedro, 16,647,000 feet. The valuation of the lumber shipped was about $570,000.

—A cable forty miles in length is being run through the snowsheds in the Sierras, for the use of the telegraph service. It will be an improvement over the old system of stringing the wires on poles. Nothing short of a landslide will interfere with or cause a break in it.

—During the week the proposed San Francisco and San Joaquin Railroad has received big impetus by substantial subscriptions of stock by prominent residents of this city, aggregating $1,300,000. It is considered certain that the project will now be pushed to successful completion.

—The new water works at Astoria, Or., will cost $150,000. The Pacific Paving Co. have the contract for grading and clearing, building bridges and culverts, digging and covering the pipe trenches and excavating the reservoir, for $19,740; lining the latter and building gate and power house, $16,207. The work begins March 1st.

—The valuation of foreign exports at Port Townsend last month was $689,501, and that of imports $124,343. The customs receipts from all sources were $16,890.45. The value of goods from British Columbia and Oriental countries passing through the district in bond and destined to Eastern cities was $522,335.13, of which amount goods, consisting principally of tea, to the value of $423,970.35 were admitted free of duty.

A SHARK STORY has recently been given out by the house of Grace & Co., of New York. It is in regard to a package of important papers that were lost overboard from the steamer Capac at Rio Janeiro, a considerable time ago, when she was on fire at that port. The papers were given up for lost, but quite recently some one killed a giant shark at Terre de Bas les Saintes, and among the bric-a-brac in his interior were the Capac's papers. They were turned over to a French resident, who sent them to the London Board of Trade, which delivered them to M. P. Grace, of the firm's London house, who advised the people here of their recovery. The fact that Terre de Bas les Saintes is up in the West Indies, some three thousand miles from Rio, makes the story all the more interesting.

THE U. S. Supreme Court has decided that the statute of limitations applies to claims growing out of patents the same as any other claims.

FOR SALE.

1 Latest Improved Bruckner Furnace.
2 Chlorinating Cylinders of cast iron, lead lined.
1 set Krom Rolls.
The above in use but a short time. For sale cheap. Address L. C. S., Box A,, Mining and Scientific Press Office, S. F.

OUR PIPE IS FOR SALE.

For Hydraulic Mining and Irrigation Purposes Our Sheet Iron and Sheet Steel Riveted Water Pipe Is Unexcelled.
We Have Also a Large Line of the MATHESON JOINT (Lap-Welded) Pipe, for Which We Are Agents.
Our Prices Are Low; Our Pipe Is Superior, and We Want More Business. May We Quote You Prices?

PIPE FITTINGS, TOO.

RISDON IRON WORKS,
SAN FRANCISCO, CAL.

Attention Miners!

W. W. MONTAGUE & CO.
—ARE MANUFACTURERS OF—
Riveted Iron and Steel
Water Pipe
For Hydraulic Mining, Mills and Power Plants.
IRON, CUT, PUNCHED AND FORMED, AND TOOLS SUPPLIED FOR MAKING PIPE ON THE GROUND WHERE REQUIRED.
309 to 317 Market Street, San Francisco.

FRANCIS SMITH & CO.,
—MANUFACTURERS OF—
SHEET IRON & STEEL PIPE
FOR TOWN WATER WORKS.
Hydraulic, Irrigation and Power Plants, Well Pipe, Etc., all sizes.
130 BEALE STREET, SAN FRANCISCO, CAL.
Iron cut, punched and formed, for making pipe on ground where required. All kinds of Tools supplied for making Pipe. Estimates given when required. Are prepared for coating all sizes of Pipes with a composition of Coal Tar and Asphaltum.

GREASE CUPS

"SUCCESS BRINGS SUCCESS."
Did you ever stop to think what this means? Did you ever notice how the "successful" firm transacts its business? It does it through "successful" channels. The Lunkenheimer Company is said to be a "successful" firm; that their specialties are a "success;" that the name "Lunkenheimer" on Brass Goods means "success." You can judge for yourself by sending for their new Catalogue. No steam user should be without one. Gratis upon request. We don't want all your trade, only a share.
WE HAVE COME TO STAY.
THE LUNKENHEIMER COMPANY.

MINING LAW, MINE EXAMINATIONS, METALLURGY, ASSAYING AND ANALYSIS.
"Consulting Associate Mining Attorney at Law."
Will examine and report upon "Title and Exact Value" of Gold, Silver, Lead, Coppor, Coal, Iron, Clay or other Mineral Properties IN ANY PART OF THE WORLD. Any information mining men may desire to know, relative to the MINERAL or COAL resources of the entire Pacific Northwest, will be honestly given.
Dr. Willis E. Everette,
1318 E Street,
Tacoma, State of Washington, U. S. A.

The Explorers' and Assayers' Companion.
A Third Edition of Selected Portions of the "Explorers', Miners' and Metallurgists' Companion."
By J. S. PHILLIPS, M. E.
A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying and Metallurgy.
The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay has been kept as free from formulæ as possible. The work is written for practical men, and all the explanations and discriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.
Price $6.00 postpaid. Sold by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco

W. H. Birch & Co. (Incorporated)
Manufacturers of
Passenger and Freight Elevators,

Improved Corliss Engines,
Mining Machinery,
Cable Railway Machinery.
119 BEALE STREET, SAN FRANCISCO, CAL.

BACK FILES of the MINING AND SCIENTIFIC PRESS (unbound) can be had for $3 per volume of six months. Per year (two volumes), $5. Inserted in Dewey's patent binder, 50 cents additional per volume

Electrical Progress.

What Is Electricity?

It is often easier to name the sources from which a well-known thing is derived, and the effects it is capable of producing, than to explain what it really is. Hence the difficulties which have attended all attempts to define electricity are not without precedent or parallel. Faraday, Franklin, Maxwell, Hertz and others have contributed largely to our knowledge in this field, and our impressions of the subject have undergone more or less change; but to-day we are apparently as far as ever from a distinct, positive understanding of the true nature of this mysterious agent. Professor Rowland discusses "Modern Theories of Electricity" in *Engineering Magazine* in an intelligent, if not satisfactory, way; but the best he can do is to offer us negative and fresh problems.

Recognizing the trammels of tradition, and realizing that he cannot offer anything very tangible in the place of what he takes away, he confesses that "we cannot free ourselves from these old theories, and exactly suit our words to our meaning." At the very outset, he insists that "there is nothing more certain to-day than that electricity is not a fluid," and pronounces the term "electric currents" "unfortunate." And then he shows that just as Newton required the existence of an ether, filling all space, to account for the force of gravitation, so we must join Faraday in presupposing that same medium as a means for all the electric and magnetic actions we witness. That these actions occur along what we call "lines of force" or "tubes of force" has long been known. Maxwell's calculations as to the electro-magnetic nature of light and its transmission in waves, wonderfully confirmed by the demonstrations of Hertz, render the ether still more necessary to the solution of the problem. But the question then arises, how can "lines of force" arise in the ether? What is the ether, anyhow? Swift as light and electricity are in their movement through space, their journey from the sun to the earth requires appreciable time—eight minutes, at least; while gravitation acts instantaneously. That is an inexplicable inconsistency. Moreover, the ether does not retard the progress of heavenly bodies moving through it, nor impede the light rays from more distant objects which pass near to planets that might be supposed to attract it, in layers denser than the average, around them. Apparently, then, the ether is without weight, and we are forced to conclude: "Ether, then, is not matter, but something upon which many of the properties of matter depend. * * * Where is the genius who will give us an ether that will reconcile all the phenomena with one another?"

Tesla's "Oscillator."

Tesla's latest invention, the "Oscillator," is described as one of the most remarkable appliances of the age, consisting of "the core of a steam engine and the core of a dynamo combined, making a harmonious mechanical adjustment." This combination, says an enthusiastic admirer, constitutes a machine which has in it the potentiality of reducing to the rank of old bell metal half the machinery at present moving on the face of the globe. It may come to do the entire work of the engines of an ocean steamship within the small space they occupy and at a fraction of their cost, both of construction and operation. It will do this work without jar or pounding, and will reduce to a minimum the risk of derangement or breakage. There is nothing in the whole range of mechanical construction, from railway locomotives to stamp mills, which such an invention may not revolutionize. The essential characteristic of the machine is the application of the pressure of steam to produce the extremely rapid vibration of a bar of steel, or piston, which, in turn, is so adapted to a set of magnets that the mechanical energy of the vibration is converted into electricity. The extraordinary result is that practically an absolutely constant vibration is established, and a power is obtained greatly beyond that obtainable in the most costly expansion engines using a similar amount of steam.

Besides, it is said, saving in mechanical friction the thirty-five per cent of loss in the working of the engine, the fifteen per cent of loss in belt friction, and the ten per cent of loss wasted in the dynamo, making altogether an addition of sixty per cent to the available energy obtained from the steam for the purpose of producing electricity, it is simpler, lighter and smaller than the mechanism it is designed to replace, absolutely constant in its action, automatically regulated and subject to the least possible amount of wear and tear. The utilization of this machine in any branch of industry would, it is claimed, result in an appreciable lowering in the cost of production, and it is thought quite possible that its first general employment may be in electric lighting.

Recent Tests of the Telautograph.

For reasons not obvious, Dr. Gray's telautograph is attracting more attention abroad than in the inventor's own country. This is the apparatus by means of which writing or outline drawing on the tablet of a sending instrument is reproduced in fac-simile, on a corresponding instrument, electrically operated, at a distance. Each stroke, dot and dash is repeated automatically by a pen which follows the movements of the sender's stylus, and the likeness is so accurate that the chirography of a person at one end of the line may be recognized at the other by any one already familiar with it. Detailed reports are received of a recent test made between Paris and London, over a line 312 miles long, and including twenty-three miles of submarine cable (across the English channel) and five and a half miles of buried conductor (in the city of Paris). In England overhead wires were used. "Bichromate" batteries supplied the needed current at the northern terminus and Calland cells and storage batteries at the southern. Excellent results were secured. The highest speed attained was at the rate of thirty-three words a minute, and the writing was then rather ragged, though legible. This was slower work than is possible in ordinary hand telegraphy, to say nothing of automatic sending. But something else was gained instead of speed. The special value of this system is that it does not require a trained operator to use it. Fallible human intermediaries may therefore be eliminated, and absolutely faithful repetitions of a message or signal be guaranteed. A business manager, public official of high station, any one in a responsible position, in fact, may indite with his own hand a communication with the certainty that "what he says goes," and the recipient has a faithful record to preserve, if necessary, for his own protection.

ELECTRIC LIGHTS may now be shut off automatically at any hour in the night, and each one at a different hour, if necessary, by means of switches operated by alarm clocks in the hollow parts that sustain the lights. The alarm disc is set for the proper time. It is necessary, however, for a man to go around every day and wind up the clocks.

ON the railways in Denmark, the cars are lighted by electricity supplied by storage batteries. These latter are charged only at terminal stations. As the country is so small that the slowest trains only require about four hours to go from end to end of a road, this plan is quite feasible. It would not be so in this country.

A METHOD OF SILVERING GLASS has been invented in Germany, by means of which light is reflected from one surface, but is transmitted when falling on the other. In fact, it produces a transparent mirror. Such glass is admirably adapted for use in office windows on the street level.

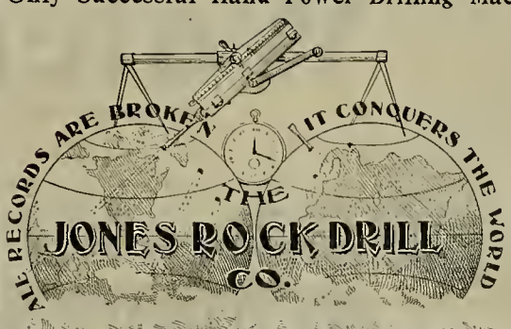
THE JONES ROCK DRILL

IS THE

Only Successful Hand Power Drilling Machine Ever Invented.



It is strong, durable, reliable, simple, compact, light, easily handled and operated by one man, and will reduce the cost of rock drilling at least Fifty per cent.

Our handsomely illustrated pocket catalogue fully explains the features and workings of the drill. It should be in the hands of every mine owner, leaser, contractor and prospect or in the West. *Sent free on application.*

If you are interested in Rock Drilling Correspond with us.

WE CAN SAVE YOU MONEY.

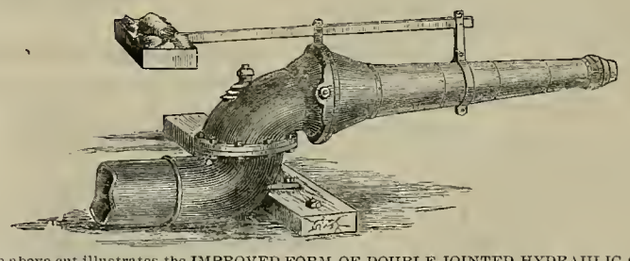
WATER 
WHEEL

CASCADE WATER WHEEL

Adapted to all heads, from 30 FEET TO 2000 FEET. Our experience of 33 YEARS in the water wheel business enables us to suit every requirement of water power plants. Send for illustrated pamphlet. This new wheel has given an unequaled Economy in Water.

JAMES LEFFEL & CO. Springfield, Ohio, U.S.A.

IMPROVED FORM OF HYDRAULIC GIANTS.



The above cut illustrates the IMPROVED FORM OF DOUBLE-JOINTED HYDRAULIC GIANTS which we manufacture, and which are pronounced far superior to the SINGLE-JOINTED style. The latter, however, we furnish when requested. Prices, Discounts and Catalogues of our specialties of Hydraulic Mining Machinery sent upon application.

JOSHUA HENDY MACHINE WORKS, 42 Fremont St., San Francisco.

The Whirl of Fortune's Wheel.

In connection with the gold strike at Leadville, C. B. Dennis gives an incident coming under his own observation recently in the East which illustrates the strange ups and downs of mining life. Fifteen years ago an acquaintance of his was at the head of a mining company then operating at Leadville. This company did considerable development work and secured patents to a number of claims, but as success did not crown its efforts the stockholders became discouraged and the claims were abandoned.

A short time ago this gentleman received a letter from Leadville, in which he was offered $500 for one of these old claims. That set him to thinking, and he made up his mind to go out to Leadville, take a look over his old stamping ground and see what was up. As a result he discovered that the claim in question adjoined the Little Johnny.

The title to his old claim was in bad shape, and he discovered that it would require $8000 to clear it up. He called a meeting of the stockholders, laid the facts before them, and expressed his willingness to contribute his share of the money necessary to clear the title and develop the property, but when he informed them that $100,000 might be required for development work they declined to undertake the hazard. He then bought them out for small sums and went ahead with the development himself. A short time ago he had a bona fide offer of $1,250,000 for that abandoned mine, and refused it.

It is incidents like this that keep men trailing over the Western mountains from youth to age.

The Inventor.

In a recent address Alexander Siemens said that it is a popular superstition that the inventors are heaven-made, and that they can produce useful novelties to order in any branch of manufacture where a want exists, if only their attention is drawn to it. "The history of the invention of the steam engine," he said, "is a well-known illustration of the point I wish to emphasize. According to the popular version, Watt, a small boy, saw the lid of a teakettle moving up and down, when the water was boiling, and this suggested to him the construction of a steam engine. As a matter of fact, Watt made himself acquainted with what had been done before (a point altogether ignored in the popular version), and had to work very hard before he brought his invention to a successful issue. His example is typical of the true method of progress, and we may generally say that in order to approach a problem with the most certain prospect of success it is necessary:

"1. To define, as accurately as possible, the want that exists, or the particular object that is to be attained.

"2. To be well acquainted with the scientific principles which come into play.

"3. To know how the want is met, or the object attained in practical life.

"4. To find out what proposals have been made by others in the same, or in a similar case.

"A careful attention to these requirements will prevent much disappointment and waste of energy, as will be obvious to all of you without further explanation."

"It is to be noticed," writes a correspondent of *Industries and Iron*, "that the gas press organs become much elated on the occurrence of any small hitch or accident in connection with electric lighting, the account of which is eagerly pounced upon and magnified in every way possible. I think that the electrical papers might, with equal justice and expediency, publish for the benefit of the electric lighting public the accounts of those gas catastrophes which one rarely passes a week without seeing in the papers. I will undertake to say that the accidents in connection with gas, involving loss of life and injury to property, occurring in a month, are more numerous and disastrous than the accidents with electricity in a year. A 'Gas Accident Calendar,' if once entered on, would, in my opinion, rapidly assume imposing dimensions."

A Year's Quicksilver Product.

The estimated production of quicksilver in California for the year 1894 is as follows:

Mine.	*Flasks.*
New Almaden	7,235
Napa Consolidated	4,930
Great Western	5,341
Great Eastern	1,368
Standard	4,214
New Idria	1,005
Ætna Consolidated	3,575

Product, 1894	30,579
Product, 1893	30,551
Product, 1892	27,993
Product, 1891	22,886

A NEW process of extracting gold from auriferous ores, by means of bromine, is reported elaborated by C. Lorsen. The difficulty hitherto associated with the use of bromine for this purpose has been the obstacle in the way of its recovery, and the process, therefore, has been too expensive for practical use. Herr Lorsen, however, now electrolyzes a solution of potassium bromide, and obtains an alkaline solution which contains hypobromide and bromate, which is capable of dissolving gold. The ore is treated with excess of this solution by rotating cylinders; the solution is then filtered, the gold precipitated by passage over a mixture of iron and coal, and the solution, which now mainly contains potassium bromide, is electrolyzed once more, and again used for extraction.

Mining Share Market.

SAN FRANCISCO, Jan. 31, 1895.

The week was a good one on the street, the market in the main being strong and active. The Con. Cal. & Va. assays show an improvement of $2 per ton. But 653 shares were delinquent at the Savage assessment sale. The Alta mill was started on Monday. Heavy snow in the Sierras in the early part of the week cut off mail communication.

At the annual meeting of the Belcher 71,867 shares were represented and the following officers elected: President, James Newlands; vice-president, A. K. P. Harmon; trustees, J. P. Martin, George D. Edwards, James Newlands Jr, C. L. Perkins was re-elected secretary and W. E. Sharon superintendent. The secretary's financial statement showed a credit December 31st of $2816, with December mining expenses not paid.

During the year 685 tons of ore were worked at the Brunswick mill, which netted $14,929.

The Homestake Mining Company paid a 25-cent dividend on the 25th. Previous dividends were 20 cents a share.

The following illustrates the changes of the week:

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING JANUARY 22, 1895.

532,869.—GAS ENGINE—Covey & Haines, Stockton, Cal.

532,959.—CLOSET SEAT, ETC.—F. G. Higb, S. F.

532,898.—BUCKLE—W. A. O'Bar, Everett, Wasb.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

HAIR CLIPPING MACHINE.—Charles W. Babcock, Portland, Or. No. 523,628. Dated Jan. 15, 1895. This invention relates to improvements in hair-clipping machines of that class in which a toothed cutter plate is adapted to be reciprocated over a fixed comb plate. The object of the invention is to provide a machine which can be placed flat upon any part of the head and operated by means of handles without the necessity of any rotary joint to change the position of the clipper with relation to the handles, and to so construct the machine that the plates may be separated from each other, the different parts easily adjusted, taken out or replaced. It consists of the comb plate fixed to one of the pair of bandles, and channels transversely upon the upper surface, a cutter plate, a tongue extending transversely between the cutter and comb plates lying within the channel having its front and rear edges adapted to form a tongue and groove engagement with the cutter plate, and a shank or spindle connecting with the other bandle having a rocker arm fixed to it and engaging the cutter plate.

P. T. Taylor & Co.

Successors to Van Drake & Taylor.

Van Drake & Taylor, general machinists of this city, have dissolved partnership. P. T. Taylor, having purchased the interest of A. J. Van Drake, will continue the business at the old place, No. 523 Mission street. This shop is one of the best equipped on the coast for doing fine and experimental work of all kinds. Inventors will find this an excellent place in which to work out and perfect their ideas, while manufacturers generally will find it advantageous to avail themselves of the fine working machinery in use here. Particularly will this be the case with those having gears to cut, as a new Gould & Eberhardt gear cutter of large capacity is at their service at very moderate rates.

Every Inventor Wants a Good Patent

Or none at all. To secure the best patents Inventors bave only to address DEWEY & Co., Pioneer Patent Agents, No. 220 Market St., San Francisco.

There are many good reasons why Pacific Coast Inventors should patronize this Home Agency.

It is the ablest, largest, best, most convenient, economical and speedy for all Pacific Coast patrons.

It is the oldest on this side of the American continent, most experienced, and in every way reliable.

Conducted from 1863 by its present owners (A. T. Dewey, W. B. Ewer and Geo. H. Strong), this agency has the best knowledge of patents already issued and of the state of the arts in all lines of inventions most common on this coast.

Patents secured in the United States, Canada, Mexico, all British colonies and provinces, England and other civilized countries throughout tbo globe.

Caveats filed, assignments duly preparod, examinations made, and a general Patent Agency business conducted.

Established and successfully and popularly conducted for nearly thirty years, our patrons number many thousands, to whom we refer with confidence, as men of influence and reliability. Old and new inventors are cordially offered tbe complimentary use of our library and free advice, etc. No otber agency can afford Pacific States inventors half the advantages possessed by this old, well-tried and experienced firm.

20-Stamp Mill for Sale.

In Southern California, a 20-stamp Gold Quartz Mill, with engine, boiler, self-feeders, rock-breaker, etc.

As the premises are adjacent to Railroad, the Mill could be conveniently removed. Can be bad at low price for cash. Address: "Quartz Mill," care MINING AND SCIENTIFIC PRESS, San Francisco.

Assessment Notices.

GOULD & CURRY SILVER MINING COMPANY—Location of principal place of business, San Francisco, Cal.; location of works, Virginia, Storey county, Nev.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 17th day of January, 1895, an assessment (No. 75) of fifteen cents (15c) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, room 69, Nevada block, 309 Montgomery street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 19th day of February, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on TUESDAY, the 12th day of March, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

ALFRED K. DURBROW, Secretary.

Office—Room 69, Nevada block, 309 Montgomery street, San Francisco, Cal.

REED MILL AND MINING COMPANY—Location of principal place of business, San Francisco, California. Location of works, Ferguson Mining District, Helene, Lincoln County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 31st day of December, 1894, an assessment (No. 1) of two (2) cents per share, was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, room 33, tenth floor, Mills Building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 28th day of February, 1895, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on WEDNESDAY, the 3d day of April, 1895, to pay the delinquent assessment, together with the cost of advertising and expenses of sale.

By order of the Board of Directors.

JOHN H. ISHAM, Secretary.

Office, Room 33, tenth floor, Mills Building, San Francisco, California.

BULLION MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Virginia district, Storey county, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 21st day of January, 1895, an assessment (No. 44) of 10 cents per share was sold on THURSDAY, the 21st day of March, 1895, levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the company, Room 21, No. 331 Pine Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 26th day of February, 1895, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

R. R. GRAYSON, Secretary.

Office, Room 21, No. 331 Pino street, San Francisco, California.

INYO MARBLE COMPANY OF CALIFORNIA.—Location of principal place of business, San Francisco, California; location of works, Inyo, Inyo County, California.

Notice is hereby given, that at a meeting of the Board of Directors held on the 21st day of January, 1895, an assessment (No. 39) of ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, Room No. 13, third floor, Mills Building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 6th day of March, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on FRIDAY, the 5th day of April, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

W. W. SARGEANT, Secretary.

Office—Room 13, third floor, Mills Building, San Francisco, California.

DUMBARTON LAND AND IMPROVEMENT COMPANY.—Location of principal place of business, San Francisco, California. Location of works, in the counties of Alameda and Santa Clara, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 22d day of January, 1895, an assessment (No. 7) of 12½ cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, No. 214 Pine street, room 55, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 28th day of February, 1895, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on THURSDAY, the 21st day of March, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

Steadily Sinking.

Col. E. J. Corthell, who is now making surveys for a $5,000,000 bridge across the Mississippi, near New Orleans, says that the city is steadily sinking. He says that there is a movement on foot among eminent engineers to have an investigation made into the delta country, with a view to ascertain how much sinking there has been during the last thirty years. It is a fact that the entire delta country is gradually sinking. From a number of bench marks made by surveyors years ago on trees, etc., on the gulf coast, and a comparison of the mean level of the gulf now with what it was twenty years ago, in connection with the present bench marks, the fact has developed that the delta coast has sunken at least a foot in the past thirty or forty years. There is no doubt that the city of New Orleans is some six inches lower now than it was forty years ago. The intention is to ascertain the exact sinking of the earth and to investigate the causes which have produced it.

THE figures show that the two cruisers, the "Cincinnati" and the "Raleigh," which were built by the Government, cost $1,227,565.94 more than contractors offered to build them for. In other words, three cruisers could have been built by contract for what two cost when the Government tried to do its own work, and they could have been completed in less time.

GLADSTONE MINING COMPANY, FRENCH GULCH, Shasta Co., Cal.,
C. J. Clark, M. E., Gen'l, Supt. Dec. 12, 1891.

MESSRS. ADAMS & CARTER, San Francisco, Cal.—DEAR SIRS: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the FRUE in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for TWELVE MONTHS. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to to mention. In order to give an idea of the work they are doing here, I will state that the ore has varied monthly from $3 to $20 per ton and the tailings from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six-foot Frue Vanner too highly, and it is the only table that I would have in my mill. C. J. CLARK, Gen'l Supt.

The McGlew Ore Concentrator Company.

PATENTED SEPTEMBER 19, 1893. CHEAPEST, SIMPLEST, MOST DURABLE AND CLOSEST SAVING CONCENTRATOR IN USE. FRANK BARRERE, Secretary and Manager.

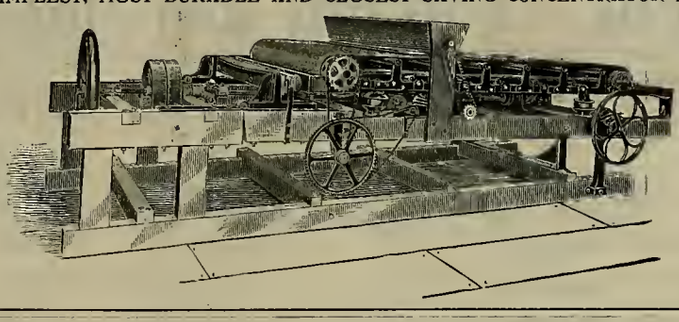
Can be seen in operation at the Company's works, 132 Main Street, San Francisco.

Office, 116 Davis Street.

NINETY-FOUR AND ONE-HALF PER CENT
—SAVED—
ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness, combining both Side and End Motion with a Bumping Belt.
SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILST IN OPERATION.
CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE.....$350 EACH
Including prepared canvas belt 4 ft. 6 ins. wide.



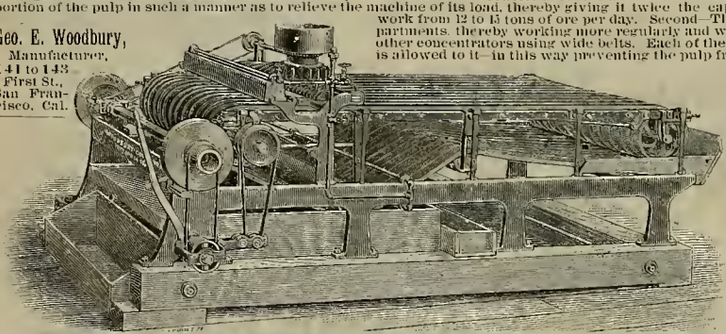
FALLS MINE, IGO, SHASTA CO., CAL., May 25th, 1893.
THE MCGLEW CONCENTRATOR COMPANY:—I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years' experience with different concentrators, I believed them to be the best.
Now, after a thorough trial of the McGlew Ore Concentrator, on ores difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ores. It is doing CLEANER and CLOSER work than I had believed possible for any concentrator to accomplish.
Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * iron West ledge, a saving by your concentrator of 94½ per cent; from East ledge, * * * a saving of 92 per cent. The concentrator runs very easy and requires but slight attention. One man attends to rock breaker, crusher and concentrator.
You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily ecommend it to the mining public. Yours respectfully,
E. L. BALLOU, Propr. Ballou Reduction Works.

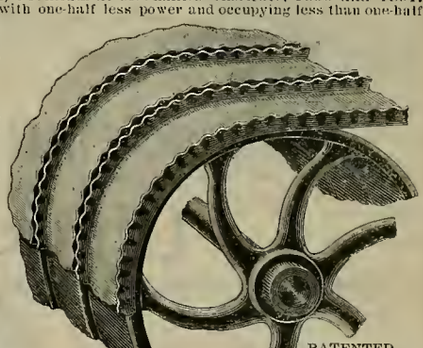
THE WOODBURY ORE CONCENTRATOR WITH IMPROVED BELTS

was awarded the Highest (Bronze Medal) Premium at Mechanics' Institute, 1890 and 1891. MORE THAN DOUBLE THIS CAPACITY with one-half less power and occupying less than one-half the space of any other concentrator. Built of best Steel and Wrought Iron. Strong and durable. **Price $575 f. o. b.** Send for Catalogue and Testimonials.

The annexed cut shows the belt in its improved form, which consists of corrugated edges, to form an expanding top edge. THE IMPROVED MACHINE HAS THE FOLLOWING MERITS: First—The Improved belts, which consist of seven, are constructed and arranged so as to allow each belt to receive a portion of the pulp in such a manner as to relieve the machine of its load, thereby giving it twice the capacity of other concentrators, and enabling it to work from 12 to 15 tons of ore per day. Second—The machine equalizes the load by several compartments, thereby working more regularly and with much less attention than is necessary to give other concentrators using wide belts. Each of the belts on this machine takes care of the pulp that is allowed to it—in this way preventing the pulp from running to the lower side of it, as is the case when a machine becomes out of level where wide belts are used. Third—The belts run on a perfect line, needing no adjustment to prevent their running from side to side, as in other concentrators. Fourth—The belt surfaces are improved by indentations and corrugations, causing the Concentrator to save fine sulphurets and quicksilver, and perform close work. Fifth—The belts have fluted or corrugated edges, to form an expanded top edge, which effectually prevents from cracking. Sixth—The feed arrangement is perfect. Seventh—The machine is constructed of iron, with steel crank-shaft self-oiling boxes, and everything made in the most thorough manner, enabling it to run with very little attention or wear.

Geo. E. Woodbury,
Manufacturer,
141 to 143
First St.,
San Francisco, Cal.





PATENTED, Aug. 18, 1891.

This Concentrator took the 1st prize at the San Francisco Mechanics' Institute in 1890, 1891 and 1892, and at the California State Fair in 1892; it took the 1st prize at the World's Columbian Exposition, 1893, and at the San Francisco Midwinter Fair, 1894.

AND PACIFIC ELECTRICAL REVIEW.

VOLUME LXX. Number 6. SAN FRANCISCO, SATURDAY, FEBRUARY 9, 1895. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

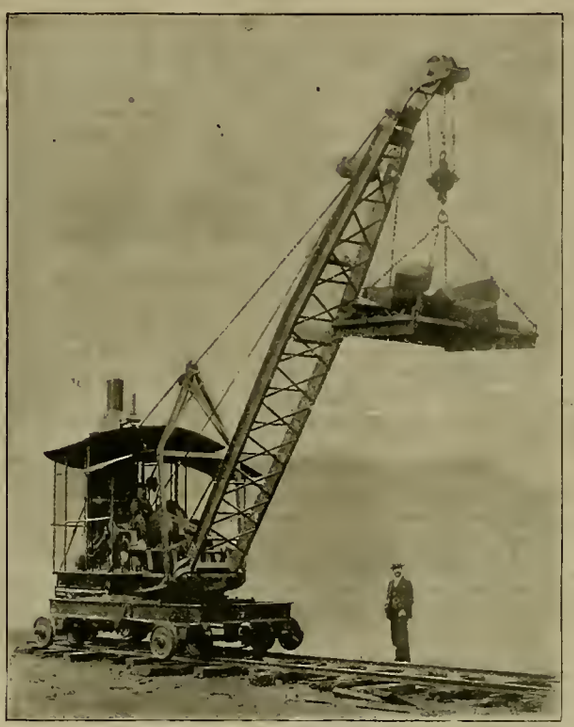
The "Lancaster" Hoister at Rocky Bar, Idaho.

The "Lancaster" combination hoisting machine, shown at work as a steam crane on the accompanying cut, taken from a photograph, is one recently designed and built by James H. Lancaster, 39 and 41 Cortlandt street, New York, for the Bear Creek Alluvial Gold Company of Rocky Bar, Idaho.

It is there used chiefly for raising boulders and rock from the creek fifty feet below the track on which it travels and works. The illustration shows the machine with a load of boulders and rock weighing four tons on a platform six feet square and five feet high.

The boulders are lifted from the creek and then run back on the track 200 feet, swung completely around and automatically dumped by tipping one side of the platform by a chain connected to and operated by the second drum of this double drum hoister.

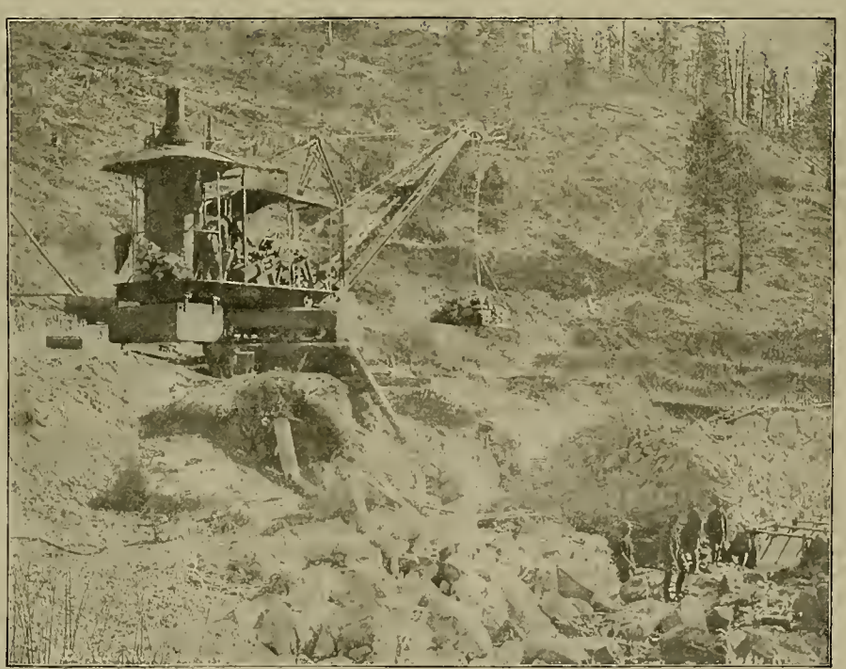
The hoister is self-propelling in both directions on a 4-foot 8½-inch, 8 or 10 foot gauge track, and has eight adjustable traveling wheels to suit the gauge. It rotates the platform carrying the engine, boiler and loaded boom completely around upon a 7-foot 6-inch turntable mounted on the steel truck. The machine travels about four miles an hour, derricks the loaded 30-foot steel boom in and out and swings it around the entire circle in thirty seconds. The swinging or slewing, derricking and traveling motions of the machine are simultaneously operated and independently reversible, and it is so balanced that no perceptible jarring or rocking of the platform occurs while rapidly picking up or dropping the heaviest load at the extreme radius.



THE LANCASTER "1895" HOISTER.
Seven tons' load, thirty-foot boom.

This 1895 combiuation "Lancaster" hoister, handled by one man, automatically works a grapple of 1¼ cubic yards on a 25-foot boom, a 1¼ yard on a 30-foot boom and a 1 cubic yard grapple ou a 35-foot boom, respectively, and makes seven deliveries of a well-filled bucket from a sand, gravel or mud pit thirty feet deep to cars or scows at any point or position within the entire radius every five minutes.

A steam shovel of the "Lancaster" patent steam-actuated, double-speeded construction of 1 or 1¼ cubic yard capacity can also be connected to and be rapidly operated by one man with the same hoister and changed from or to a steam crane, shovel or grapple (clam shell or other style) inside of thirty minutes. This combination machine can also be readily detached from the steel car-frame shown and transferred to and fixed upon the deck of a scow or barge and rapidly operated from it and used either as a crane or for working a grapple or a dipper.



THE "LANCASTER" HOISTER AT ROCKY BAR, IDAHO.

The engines are reversible and set at a slight angle to permit the compact arrangement shown of gears and frictions and the center-pin or steadying post, around which the whole machine rotates. The pair of engine cyliuders are 9 inches in diameter by 12-inch stroke and mounted on a frame. Extension arms or lateral supports are carried at both front and rear ends of the truck, which slide in flush when not in use, aud outwardly as needed up to fourteen feet in width. These four adjustable steadying accessories are available in case of any tendency to tip, when rapidly lifting and swinging excessive loads at a great radius. Winch-heads are placed on each side of the machine for general hauling purposes.

These hoisting and digging machines are also operated in connection with the new "Lancaster" placer gold amalgamator and concentrator which treat low-grade placer diggings, tailings or pulverized ore from either stamp mills or rolls at the rate of one cubic yard and upward a minute, at low cost with a minimum supply of water or compressed air.

A MINER, who owns a three-fourths interest in a claim that he wants patented, writes, saying that the owner of the other one-fourth doesn't want the claim patented and refuses consent. He wants to know the best thing to do. Go ahead, and get your claim patented in the joint name of yourself and the owner of the one-fourth. He may or may not pay his pro rata of the expense, but that is the only way you can get a patent. The Government won't issue a patent for an individual interest and neither you nor it can compel your partner to join you in an application. But he can't prevent you getting a patent in your name and his.

IN a communication in another column, J. E. Bell, of Shasta, emphasizes the fact recently pointed out in these columns that unless prompt and effective action be taken the thus far unpatented mineral lands of the State will be controlled by a trust. The facts have been given in these columns from week to week, our Senators and Congressmen are acquainted with them, a committee in this city is doing all possible to push the people's side of the case, and every reader of the PRESS can aid in the work.

ELSEWHERE "A Miner" voices the sentiment of every mining man in the State in a protest against the proposed transfer of the State Mining Bureau to the State University. His arguments are unanswerable.

MINING has done much for this State, but the State has never done much for mining. All that it is asked to do now is to let matters alone; let the Mining Bureau go on with its preseut good work, and don't cripple intelligent effort by any wrong ideas of "economy." The good of the State should not be made to yield a personal vindictiveness.

THE annual report of the Ontario Mining Bureau is received, containing 200 pages of practical information regarding the mineral wealth of that Dominion. It is to be hoped the Dominion government appreciates the value of the institution, and, unlike the California government, will not have any proffered measures for the annihilation of its Mining Bureau.

A PRESS DISPATCH of the 5th from Sacramento says that Prof. Hilgard, the head of the agricultural department of the University of California, is preparing a bill to abolish the State Mining Bureau. We have the best authority for saying that there is no truth in the statement. Among other sensible attributes of Prof. Hilgard is the capacity for minding his own business.

A BILL passed the Assembly last Monday that will afford some cessation from the harassing of hydraulic miners so common heretofore. As at present, any inadvertent violation of the legal technicalities regarding the disposition of debris is punishable as contempt of court—the assumption being that the miner is a quasi-criminal existing only through sufferance and presumed to be a law-breaker. The bill permits appeal from findings for contempt and gives the hydraulic miners the same equitable rights possessed by other citizens. There were only eighteen opposing votes. Its provisions apply to any citizen of any occupation and permit appeal from findings for contempt not committed in the presence of the court.

THE recent national convention of manufacturers at Cincinnati, Ohio, was well attended. It was unanimously resolved to form a "National Association of Manufacturers of the United States." A second meeting will be held in Philadelphia toward the close of the year. Each State is entitled to five delegates, and one additional delegate for every $50,000,000 output of manufactured product, as appearing in the census of '90. The matter of foreign markets was given wide discussion, the sentiment being that "no matter how much our consumption of various things is compared to the consumption of the same things by the rest of the world, our productive powers outstrip our consumptive demand and we therefore need outside markets."

THE efforts of the committee on the exemption of mineral lands are bearing fruit. Mr. McGee, "Chief of Division F," has seen a great light, and discovers that he cannot continue to be so high-handed in his actions as he started out to be. "Clear List 54" contained nearly 134,000 acres of land calculated to be absorbed by the railway company. It was certified in the General Land Office as having been adjudged agricultural, and the commissioner made a report thereon, recommending approval. Investigation, however, has shown a multitude of mineral surveys and entries in the "clear list," and the Secretary of the Interior has decided that lands embraced in List 54 selected by the Central Pacific railroad, are within a clearly defined mineral belt, and has accordingly postponed the issuance of the patent pending a publication notice.

Statements Versus Facts.

Discussing "The Silver Dollar," the Louisville *Courier-Journal*, to hand, "in a powerful editorial," says:

"The purchasing power of the silver dollar, which is now equal to that of the gold dollar, would be reduced if the present policy of the treasury were abandoned. The different kinds of dollars are kept at a parity by the policy of the treasury department, which gives to the citizen the sort of a dollar he desires. The law requires that a note which calls for coin be paid in either gold or silver at the option of the holder."

The facts are in direct opposition to the statement. The Kentucky editor's zeal in defense of the Kentucky Secretary of the Treasury does not justify such distortion of fact.

The laws of the United States give the treasury department power to redeem notes calling for coin in gold or silver at the option of the Secretary of the Treasury. The holder of the notes has nothing to say in the matter. The Secretary of the Treasury may redeem all such notes presented in silver, if he chooses, and the holder of the note cannot object, nor can he refuse to take silver.

Again Mr. Watterson says:

"Free coinage means the government shall take 371¼ grains of silver, worth about fifty cents, and give a dollar for it."

It means nothing of the kind. Free coinage means that the government shall take 371¼ grains of silver, mix with it 41¼ grains of alloy, put the government stamp on it, and give it back to its owner, the government receiving 41¼ grains of silver as pay for its trouble and the government stamp.

The same article contains a third misstatement. It says:

"The passage of the Sherman act in 1890 put up the price of silver to $1.21 in about a month. Then it began to recede and is now worth from 59 to 60 cents an ounce."

The *Courier-Journal* is as mistaken in its deductions as in its direct statements. As a matter of fact, in 1890 it was thought that a free coinage law would be passed. Under expectation of this the price of silver bullion rose to $1.21. Then, when the Sherman law was passed—as a compromise in place of free coinage—the price gradually declined again. The reason for this is plain.

The Sherman law treated silver as a commodity. Like other commodities its price was governed by the law of supply and demand, and, this being the case, the price of the whole was regulated by the price of the surplus, over and above the 54,000,000 ounces bought each year by the government. This surplus, although small, being excluded from our mints and those of Europe, sold at a low valuation, thus keeping the price of the whole product down.

Tote fair, Brudder Watterson, tote fair. Nothing is gained by misstatement of such patent facts as those discussed.

Sale of a Shasta County Mine.

The Iron Mountain group of mines near Redding was sold last week to a London syndicate, represented by C. W. Fielding, for $300,000. The property comprises 1300 acres, and has yielded silver, gold and copper to the value of over half a million. A. Hill, consulting engineer of the Rio Tinto, who examined and reported on the mine, is quoted as declaring that the Iron Mountain will be worked chiefly for its copper—something new in Shasta county. He considers the Rio Tinto to have been worked 4000 years ago by the Phœnicians. That mine has yielded over $25,000,000 since '85; and though so ancient an opening is only 400 feet deep. Mr. Hill reports it as a huge deposit of sulphide of iron running two and one-half per cent copper, and that the Iron Mountain is the nearest thing like it he has seen in any part of the world.

It is the reported intention of the new owners of the Iron Mountain to displace the twenty-stamp mill now there by a large capacity smelter, treating 1000 tons daily, and employing in all between 800 and 1000 men. The ore of the mine forms a smelting base and the silicious gold ores may be used as a flux.

The proposition is of tangible merit, and the transfer and accompanying activity another instance of profitable investment of foreign capital in California mining enterprises.

A Blow at the Mining Interests.

Not since State Senator Kelley of Solano introduced a bill into the Legislature declaring hydraulic mining in California "a public nuisance" has there been so absurd a proposition affecting the mining interests of this State as State Senator Langford's bill, which is herewith presented in full:

(SENATE BILL NO. 269.)

Introduced by Mr. Langford in the Senate, January 18, 1895. Referred to Committee on Mines, Drainage and Mining Debris.

An Act

To repeal an Act entitled "An Act to Provide for the Establishment and Maintenance of a Mining Bureau," approved April, 1880, and to transfer the museum, library, laboratory and all other property of the State Mining Bureau, together with the fund provided for the maintenance, to the University of California.

The people of the State of California, represented in Senate and Assembly, do enact as follows:

SECTION 1. The Act to provide for the establishment and maintenance of a Mining Bureau, approved April 16, 1880, is hereby repealed.

SECTION 2. The Act supplementary to "An Act to Provide for the Establishment and Maintenance of a Mining Bureau approved April 16, 1880," approved March 21, 1885, is hereby repealed.

SECTION 3. The museum, library, laboratory, and all other property whatsoever of the State Mining Bureau, shall be and is hereby transferred to the custody and care of the Regents of the University of California, to be administered by them for the State of California, as part of said University.

SECTION 4. The Regents of the University of California may, in their administration of the museum, authorize the Department of Geology and Mineralogy of the University of California to carry out any investigations in the field or otherwise which may be deemed necessary for the elucidation of the geology and mineralogy of the State, or to complete the geological and mineralogical history of California.

SECTION 5. For the purpose of maintaining the Museum of Geology and Mineralogy in the city of San Francisco the fund known as the Mining Bureau fund, as described in Section 5 of the Act herein repealed, entitled "An Act for the Establishment and Maintenance of a Miniug Bureau," approved April 16, 1880, is hereby continued in force and shall be known as the "Geological and Mineralogical Fund," and the tax upon certificates of stock corporations shall continue to be levied in the same manner as heretofore, as provided by the Act entitled An Act Imposing a Tax on the Issue of Certificates of Stock Corporations, approved April 1, 1878, and shall be covered into the "Geological and Mineralogical Museum Fund" in the same manner as heretofore it was placed to the credit of the "Mining Bureau Fund" as provided by Section 5 of an Act entitled "An Act to Provide for the Establishment and Maintenance of a Mining Bureau" hereby repealed, and the said "Geological and Mineralogical museum Fund" shall be applied by the Regents of the University of California, to the maintenance and support of the said museum, and to the prosecution of such investigations into the geology and mineralogy of the State as may be authorized by the said Regents.

SECTION 6. This Act shall take effect and be in force immediately after its passage.

A Strong Protest.

The Sundry Civil Service bill contemplates a cessation of part of the regular and necessary work of the U. S. Coast and Geodetic Survey, that would be destructive to the best interests of the work. The present field force is an excellent one; the work being done is important and necessary, and any change in the personnel would be subversive of present requirements. Recognizing this fact, the Geographical Society of the Pacific has forwarded the following protest to the California Congressional delegation:

To the Senators and Representatives of California:—Senators White and Perkins, and Representatives Maguire, Loud, English, Bowers, Geary, Cannon and Caminetti, Washington, D. C.—The council of the Geographical Society of the Pacific has learned with much astonishment that the Sundry Civil Service bill presented to Congress contains estimates which propose a reduction of the field officers of the Coast and Geodetic Survey.

This council knows that a very large part of the triangulation of the combined coasts of California, Oregon and Washington has not been executed. There is more than ten years' work of triangulation and topography for all the available field officers of the survey, with a liberal appropriation each year.

Moreover, the whole coast of Alaska, exceeding *26,000 miles* of shore line, has hardly been touched, except by preliminary work and examination for the pressing demands of navigation. Recent urgent demands have been made for accurate determinations of latitudes and longitudes and measures of triangulation in the Aleutian chain of islands, as a basis for surveys that will give to navigators reliable charts of harbors, headlands, channels and dangers.

No trigonometrical or topographical survey has been inaugurated on the whole outer coast of Alaska, as the base work for hydrography, except a small section connected with the boundary line near Mount St. Elias.

The important chain of the Aleutian islands, the island groups under the peninsula of Alaska, and the outer shores from 50° 40' to the Arctic, are now visited annually by fleets of fur sealers, whalers, traders, fishermen, and by the naval and revenue vessels, and these vessels are, in the main, still using old Russian and English charts, or charts compiled from those authorities with slight additions.

This council therefore urges upon the Senators and Representatives from California the necessity for maintaining the present field force of the Coast and Geodetic Survey, which comprises men of large experience and exceptional skill.

ADOLPH SUTRO,
Mayor of San Francisco.
JAMES F. HOUGHTON.
C. L. TAYLOR.
IRVING M. SCOTT.
RALPH C. HARRISON.
JOHN PARTRIDGE, Secretary.

Concentrates.

THE two mining towns of Grass Valley and Nevada City, Nevada Co., Cal., use 96 telephones.

THE rainfall at the Kennedy mine, Amador Co., foots up nearly thirty-six inches so far this season.

THE Texas mine in Willow valley, near Nevada City, has been bonded by European capitalists, who will develop the property.

AT New Years diggings, Mariposa county, several strikes are reported. Talk is made of stamp mills and kindred improvements.

THE sale of the Golden Wonder mine, near Payson, in Tonto Basin, Arizona, for $40,000 is reported, the buyers being Colorado men.

REPORTS from Montana indicate that hundreds of thousands of dollars worth of mining machinery will be needed in that State this year.

THERE is hardly an unclaimed piece of mining ground left on Elliott creek, Or., now, and that section will be one of the liveliest camps in southern Oregon when spring opens.

THE "Lost Frenchmen" mine near Palomas, in the S. H. mountains, Arizona, has been found again. If it will only stay found, it will be unusual in the annals of lost mines.

FIFTY-FOUR THOUSAND OUNCES of gold were recovered at the Randt and 8000 ounces in other districts; total, 62,000 ounces during December. The November total was 65,000 ounces.

THE silver product of the U. S. in '93 approximated 60,000,000 ounces. It is thought that the aggregate for '94 shows a reduction of about 8,000,000 ounces from that of the preceding year.

THE Austin *Reveille* says Mark Wiggins, and those interested with him, received over $11,000 for the forty or fifty tons of ore recently shipped by them from Kennedy to San Francisco.

IT is said that S. T. Godbe has leased, for two years, all of the Pioche Consolidated property, and active work is soon to be resumed in some of the most important mines, principally the Half Moon group.

LAST Saturday, while retorting 115 ounces of amalgam at the Birney mine, near Angels, the retort exploded, scattering and losing the amalgam and seriously injuring the mill man, Jones, in the eyes and face.

A NEW concentrator, with a capacity of eight tons per day has been put in at Z. A. Moody's quartz mill near Ashland, Or. The ore from the Mattern mine will be run through it when it is ready for business.

THE Gold Nugget Mining Company has incorporated in this city. Directors—G. M. Spencer, H. L. Johnson, John Gamage, John A. Day and E. W. Strange; capital stock $1,000,000. Of this magnificent sum $2500 has been subscribed.

W. S. STRATTON has shipped from his Independence mine in the Cripple Creek district 100 tons of ore, which is expected to yield $1,000,000 at the Denver smelter. Some of the ore is rich tellurium, which runs $30,000 in gold per ton.

IN the Broken Hill Proprietary for the week ended Jan. 3d, 10,274 tons of ore were treated, yielding 858 tons of lead, containing 226,016 ounces silver; also 863 tons treated by amalgamating and leaching plants, producing 10,107 ounces silver.

THE San Diego *Union* is authority for the statement that within seventeen miles of that city there is a gold mine with a fine quartz ledge twenty feet wide, the ore of which runs from $16 to $25 per ton. That, if so, is worth development.

THE Tiger-Poorman mines on Canyon creek in the Cœur d'Alene are reported sold to an English company which has capitalized the property for $1,850,000. The mines have been large and profitable producers, since their first location nearly ten years ago.

THREE years ago, says the *Mining Industry*, every promoter in Denver advised investors to let mining alone and touch nothing but real estate. Investors got the worst of it. Now the whole crowd are working the mining racket as the only good thing. They are correct this time.

THE official statement showing that the net proceeds of the Midwinter Fair amount to over $32,000 causes the Grass Valley *Telegraph* to reflect that the managers could have well afforded to give to Nevada county a gold medal instead of the bronze one for her fine mineral exhibit at the Fair.

A BILL in the Montana Legislature fixes a standard of water measurement and the equivalent of a miner's inch. A cubic foot of water, 7.48 gallons, is declared the legal standard of measurement. One hundred miner's inches are equivalent to a flow of 2½ cubic feet, 18.7 gallons per second.

A NEW 30-stamp mill is to be built at the Silver Peak mine, Walker Lake district, Nevada, and in a few months the forty stamps now at Gold Mountain are to be added. Two steam traction engines of 100 tons capacity each will haul ore from the mine to the mill. The first $100,000 of the $500,000 purchase price has been paid.

IT is reported at Cornucopia, Or., that the O. G. M. Co.'s 100-stamp quartz mill is in danger of collapsing from the enormous weight of snow now lying upon its roof. Snow is between seven and eight feet deep there. It is customary to remove the snow as fast as it falls, but this winter, the property being in litigation, the matter has been neglected.

THE suggestion is made that the miners of California adopt a plan followed in Colorado, where each miner pays $1 per month, which amount is used in the maintenance of a hospital for the treatment of all who are injured while at work. The plan is already in force in a limited manner by several of the mines in the Grass Valley district.

A COMPANY with a million dollars' capital was incorporated in Omaha last week to work the recently discovered grindstone deposits at Edgemont, S. D. Five hundred men will be employed at the quarries. The deposit is said to be inexhaustible and the enterprise is expected to prevent further importations of Bavarian grindstone into the United States.

IN the February *Forum* A. S. Heidelbach explains "Why Gold is Exported." He says it is because "disgust of foreign investors because of recent developments in our railroad management; dismay at the condition of the Treasury and our currency, and the fear that if they invest money here they may not be able to get back as good money as they gave. He says that no change in this state of affairs may be expected until the Government goes out of the banking business and we have a more elastic currency."

THE Shasta *Courier* says more snow is stacked up in the mountains than has been known since 1861, and when the spring rains and thaws come there will probably be considerable damage to property by rushing floods. The deposit on Mt. Shasta and all the country about its base is the deepest known for years, and when the snow melts in the spring the Sacramento and McCloud will boom.

THE *Idaho Avalanche* recently announced a "popular mine" scheme, a prize to go to the mine having the most votes in its favor for the productive quality of the mine, its management, method of working, ventilation, and general advantages. The best mine in the camp got one vote, and a "mine" that has never produced a pound of ore got 165. At this juncture the *Avalanche* disgustedly announced the contest off.

IT is reported in Grass Valley that the Osborn Hill Co. has bought the Orleans mine for $100,000; that there will be no spot cash payment, but the Orleans Co. will receive $50,000 at the end of the first year and the other $50,000 at the end of the second year, with an additional ten per cent of the net revenue from the Orleans mine during the term for which payments are pending.

THE recent closing of the Everett, Wash., smelter, is the unsatisfactory outcome of a $3,000,000 investment by Standard Oil millionaires in it and the Monte Christo gold quartz mines, which proved too rebellious even as a smelting proposition. Mr. W. E. Everette, of Tacoma, long since reported adversely on the proposition, but an Eastern expert reported favorably, the investment resulting therefrom.

IN compliance with the request of Representative Caminetti, who has a bill pending to classify mineral lands, the Secretary of the Interior has sent the railroad land list No. 54, embracing 130,000 acres of Central Pacific selections in El Dorado, Placer and Nevada counties, to the local office to be posted for twenty days, so that contestants shall have notice and may file any protest alleging mineral in any of these lands.

THE Zantgraf mine, in El Dorado county, was sold last week to a company of Chicago men known as Eggleston, Mollett & Co., for $100,000. The new company will take charge immediately and will put in a twenty-stamp mill and improved machinery. Work was begun last week at the mine, and it is proposed to sink a main shaft 200 feet and run drift levels of 100 feet each.

THE Clipper Creek, Col., *Times* says that an entirely new manner of treating ores has been found at a cost that is simply nominal. The *Times* suggests that it may be a little too early to become enthusiastic over the process, but "a few of the very best men in the county are convinced that the method is all that the inventor claims for it. Should present hopes be realized, where there is one miner working now there will be twenty within a year."

FROM a private letter to a well-known resident of Butte, the *Mining and Railway Review* learns that Montana mining properties are in great disfavor in London, caused, it is said, to a large extent, by misrepresentation. Mining brokers and middlemen too often greatly exaggerate the value of their claims, which nearly always results not alone in the loss of a sale, but queers the operator with the speculator. Montana properties are all right and do not deserve the restriction above noted.

IT is not many years since there were no places on the globe less immediately connected in trade than South America and California. Now it is a familiar sight among the Andes to see a pack train. Each donkey bears a load of two packages, each of which contains forty gallons of the wine of California, which is growing constantly more popular in the interior of the continent. The animal so laden can climb the mountains with ease, and the distribution is thus readily effected to distant points.

IN a letter from Paris, Wm. H. Townsend says: "There is now a considerable boom here in Paris, in London and in Berlin in gold mines. At present it is confined entirely to South Africa, but I believe that before midsummer it will extend so as to take in the newer gold districts of the United States. The center of the movement is in London, but Paris is rapidly warming up and Berlin is just beginning. During the last four months the Frenchmen have sent over 200,000,000 francs to London for the purchase of mining shares."

THERE is a big party of men prospecting for a lost mine in the Pinacate mountains on the coast along the gulf of Sonora. The head of the party is Mr. Brewster of San Diego, the builder of the Brewster house there. He has forty burros and eleven mules, with provisions enough to last for months. He has been in that country with his outfit since last October, and expects to remain for several months yet before giving up his search. If success attends this expedition it will have broken the record, for who ever heard of a lost mine being found?

IN his decision in the case of Dibble vs. the Castle Chief Mining Company et al., Judge Gardner of South Dakota, facetiously says: "For the purpose of enabling myself to more intelligently weigh the testimony in the case I have visited the premises in controversy. And while there is much testimony to show that the value of the labor performed on each of said claims for the year 1892 exceeded $100, since inspecting said claims I am quite clearly of the opinion that if said testimony is true, the labor of miners at that time commanded a much higher compensation than does the labor of lawyers or circuit judges."

A PUZZLE is unconsciously furnished by an Arizona prospector, in a mining location sent to the recorder. The dimensions read as follows: "Commeneing at a monument of stones, being the center of the S. E. end of claim; thence E. 300 feet; thence W. 300 feet; thence N. W. 1500, being the center of N. W. end of claim; thence S. E. 300 feet; thence N. W. 300 feet; thence S. E. 1500 feet to place of beginning." The conundrum is, How much land does he locate? This may be learned by taking a piece of paper and making in their proper position the points north, east, south and west; and then following out the directions given by the location notice.

M. GRADY, the discoverer of the group of mines on "Four Mile," B. C., which bear his name, is reported to have said the Alpha and Black Bear claims, which were sold to Seattle capitalists fifteen months ago for $70,000, were being successfully worked by the new company, and that the former mine had already yielded 800 or 900 tons of ore which ran about 120 ounces per ton. He and his partners had still the freehold of five other similar claims. Several rich finds had been made during the past year at Four, Eight and Ten Mile creeks on Slocan lake, the ore containing a good deal of ruby and natural silver. Some gold-bearing ledges, containing from $40 to $300 to the ton, were discovered near the foot of the lake. The find, however, was made late in the fall and the claims have not yet been developed.

FROM Omaha comes a fairy story of a wonderful gold mine near Bannock, Montana. The legend is as follows: Many years ago P. Vandervoot, J. M. Thurston, of Omaha, and R. A. Alger of Detroit, grubstaked a prospector. Several claims were located which assayed rich in gold. Since they were located the title has been kept good by filing certificates and by the performance of assessment work. A mining engineer made a report from an investigation he had made that the property will open up an enormous vein of mineral. The ore is sulphide with quartz which carries heavily in gold. It is free milling and can be handled easily. The ore is a network of veins and covers 300 acres. The gold belt is about fifteen miles wide and twenty-five long. A stock company has already been formed, of which Alger is president and Thurston is vice-president, and active development will commence immediately.

THE Marysville Tunnel and Quartz Co. has a claim on the Yuba river opposite Timbuctoo, extending two miles up to the mouth of Deer creek, embracing the Narrows and the old dumping grounds or tailings from the hydraulic mines in the vicinity of Smartsville. The difficulty in successfully working the mine heretofore has been the handling of the inflow of water, but arrangements are now under way and nearly completed for a plant of machinery of sufficient capacity to handle any amount of water that may flow into the works by percolation or otherwise. It is the intention of the company to go down to the original bedrock of the river. The Yuba river is claimed and operated under the United States mining laws, by various companies, for a continuous stretch of more than twenty miles, many of them meeting with flattering success, the result of which has been to create quite an excitement in river mining and to turn the attention of capital in that direction. No doubt the gold is there in abundant quantities and all that is required is the application of capital and skill to possess it.

THE Good Hope Mining Company will apply another method to the Colorado river bars. Thousands of dollars have been spent in pumping plants for these placers, and, although the gravel was rich in gold, it could not be worked at a profit. The Good Hope Company will use the old irrigation wheel method of raising water, but instead of placing stationary wheels on the bank of the stream they will be operated on boats. The barges will be used fastened together, with enough space between to permit the operation of the wheels. Two wheels, with a diameter of thirty-two feet, will revolve between the barges, the shaft running across from one boat to the other. Each wheel will have twenty-two arms, and to each arm will be fastened a ten-gallon bucket. The wheels will be revolved by the force of the current and the buckets be emptied when they are turned over at the top. It is claimed that the water can easily be raised to the height of twenty-eight feet, which will be sufficient to reach the whole bar. It is estimated that the Good Hope bar contains from 3,000,000 to 5,000,000 cubic yards of gravel, yielding from 60 cents to $2 per yard. Two of the above described wheels, it is said, will wash from 700 to 1000 yards per day, and can be operated by three or four men.

"Why Are Good Mines for Sale?"—The semi-monthly bulletin of the Colorado Gold Mines Investment Company asks this question and then proceeds to answer it by telling why owners of good properties are often eager to sell. It says: "The answer may be found in a simple statement of fact. In a great many instances the owners are men whose lives have been spent in poverty and a daily struggle for existence. They know they have a fortune; they have had enough of battle and strife. They want to enjoy life. They have dreamed of a 'good time,' and they want to realize their dreams. The man, no matter whether young or old, who never before had a dollar, who suddenly finds himself the owner of property worth many thousands, has an uncontrollable desire to see his fortune in shining gold or crisp bank notes. He wants to take life easy. He wants to move out of a miner's cabin into a home provided with the luxuries of life and he doesn't want to wait. He has not been wealthy long enough to want more. He feels that he never will want more, but what he has in the way of property he wants to convert at once into cash. It may be added that there are now many prospectors climbing the mountain sides, searching for gold, who have owned great mines, sold them and wasted their fortunes having a good time."

Personal.

MR. WISHART has assumed the superintendency of the Rose Hill mine at Grass Valley.

CLARENCE KING is inspecting mines at Colville, Wash. From there he goes to Mexico.

F. W. MEDLIN is the new superintendent of the Eureka mine at West Point, Calaveras Co.

A. & C. MALTMAN AND J. MCKEON have gone to Gold Valley, Sierra Co., to start the Empire mine chlorination works.

DR. BOYSON is in the city. Rumor credits him with an intention to turn the management of the Pioneer mine at Plymouth into a stock company.

A. S. SMITH leaves this week for the Philippine Islands, where he will superintend a 100-stamp mill, now building by English gold mine owners there.

RALPH NICHOLS, superintendent of the Sutro Tunnel at Virginia City, will resign the first of next month and go to De Lamar, Lincoln Co., Nevada, where he will be superintendent of the DeLamar mines and mills.

ROBERT LAIDLAW, president of the Laidlaw-Dunn-Gordon Pump Co. of Cincinnati, was elected treasurer of the National Association of Manufacturers, which convened at Cincinnati the third week in January. Mr. Laidlaw was one of the leading spirits in organizing the association, and much of the success of the convention was due to his superior executive skill and untiring energy. The delegation was banqueted at the new plant of the Laidlaw-Dunn-Gordon Pump Co.

An Impending Danger.

To the Editor:—If this coutroversy as to what is mineral and what is agricultural land is continued much longer it will be useless, as the railroad company will have all the mineral land patented and sold. There are uow 600 sections being patented through the Redding Land Office. An examination would show a small part of this land to be agricultural. All railroad land in their grant to the Oregon line, whether mineral or nou-mieral land, is mortgaged to a Loan and Trust Co. in New York city, and there is every reason to believe that it is being patented for them; if so, there will be three or four thousand square miles of the richest mineral land in California owned by a trust company.

There is proof that the Land Department is going to give patents to all lands on the Oregon railroad whether mineral or not. Two years ago the writer was one of several parties who filed a complaint before the Land Department at Washiugton, accompanying the same with maps and affidavits in regard to the mineral character of the laud in the railroad grant from Middle Creek station in Shasta county to the Oregon State line. This complaint includes land 100 miles long by 60 miles wide, including railroad indemnity land. Affidavits were made to these facts, and they are just as true uow as they were then, viz: That there were uot forty acres of agricultural land, not already taken, in the entire tract; that there is not more than one acre in 10,000 that is agricultural; that all of the laud was more valuable for mineral than for agriculture; that it was well-known mineral land and had been known as such for thirty years.

These facts were embodied in the complaint sent, with a request that they be investigated, and, if the affidavits were found to be true, that the laud be declared mineral. After a time a long answer was received, which was in substance as follows: Complaint received, filed, investigated, and dismissed for the reason that there are uon-mineral affidavits on the land referred to. So we find that this mountainous country, rich in gold, silver, copper and quicksilver is covered by nou-mineral affidavits and can be patented as farming land! Who made those affidavits? What men perjured themselves for this corporation? is a secret that the Land Department is strictly guarding.

Orders have been received at the Redding Land Office to cancel all mineral affidavits. No notice will be given the miners who filed them before patent is issued to the railroad company. Most of the producing mines of Shasta county, on odd sections, have first been purchased from the railroad company and then patented from the Government.

If the Caminetti bill, now before Congress, to appoint commissioners to classify mineral aud agricultural land fails to pass, or if passed and the commissioners fail to do their duty, every odd section of mineral land in this State will be owued by a trust.

This commission should consist of one practical miner who understauds quartz and placer mining and is trained in prospecting for mineral, one farmer and one lawyer, and selected from the three political parties. Unless there is great care taken in selecting these men, California will have auother "special" commission as useless as the past Railroad Commission.

All the railroad land from Reddiug to the Oregon line is being listed for patent regardless of mineral land. If Congress adjourns without assisting the miners, this land will be lost to them.

The attention of the legislators should be called to this grab. The miners want the land examined, and it will be found to be mineral and not such land as the railroad is entitled to. To enter contest before the Land Office is hopeless, as the miner is compelled to prove the existence of mineral in paying quantities on each and every one of the smallest legal subdivisions. The magnitude of this steal cannot be estimated. Millions of dollars will be taken out of these mountains every year, if they are open to exploration and possession by the miner.

The attention of our members in Congress and our Senators should be called to this injustice.

The scheme is to have a trust own and control the mineral land of California, as that is about the only industry not controlled in that way. As to the rulings of the United States Land Department, the less the miners have of them the better, as each succeeding one only increases the difficulties of the miner.

Give the miners the Caminetti bill and these classifying commissioners not appointed by a political "pull," and they will get justice. J. E. Bell.

Shasta, Feb 4, 1895.

At the Mausfield copper mines in Germany, immense reservoirs for compressed air are cut out of the rock, near the machinery to be operated thereby, and lined with cement. There are eight of these receivers, from 1235 to 3950 cubic feet capacity. A rock chamber of 2200 cubic feet capacity costs, it is stated, only one-third as much as an iron receiver of equal size.

An Earnest Protest.

To the Editor:—The sentiments you expressed iu the last issue of the Press in regard to the proposed transfer of the State Mining Bureau to the State University at Berkeley are just those of every miner who has had an opportunity of experienciug the benefits of the Bureau, which has now become the source to which we look for instruction and information and has in fact become the educator of the miner. It is as you say the only represeutative institution of the miners of the State.

I have met with the reports and bulletins issued by it in every miuiug camp in my travels, and their well-worn pages illustrate the interest with which they have been read, as they have been passed from hand to haud aud have served to teach the wielders of the pick and shovel much that was useful and beneficial in their work.

During the past two months, while passing a period of iuactivity in the city awaiting the advent of spring to permit of the resumption of work on my miuing property, I have resorted to the Mining Bureau on Fourth street, where I have had resource to its file of mining papers and library of valuable books, aud reaped benefit and instruction that will be of great use to me in the future. I meet at the Bureau many miners, like myself, in pursuit of information, freely given, and experience the utmost courtesy and attention.

Aside from its valuable reports, the bulletins issued on "Methods of Mining Timbering," "Locatiou of Mines," instructing the miner how to take up claims, etc., the bulletin ou "Gas and Petroleum," and the last and most valuable pamphlet on the "Cyanide Process," which gives information long sought and never before obtainable. The eagerness with which these reports and bulletins are sought for is illustrated by the hundreds of people interested in mining calling to obtain them. Again, it is not only those who call at the Bureau, but the hundreds of applications by letter from miners in the interior. Copies of the reports and bulletins are sent to every mining superintendent throughout the State and are gratefully received.

The idea of transferring the Bureau in part, or as a whole, to the State University is tantamount to its entire wiping out, for how many miners seeking information from its books or orally would go to Berkeley or to the Park to study the mineral exhibit and compare the character of its ores as an educator?

The scheme is absurd, so far as the Bureau ever being of any further use to the miners of the State is concerned. Again, on the score of economy, a staff of experts must be engaged all the same and paid all the same, for it is ridiculous to suppose there is any material at the University to do this duty. Where has it had its experience? The idea of its being converted into an instructor to the students is equally absurd. Of what value would the examination of a mine by one of the University students be to the miner or investor? It would be placing the whole objects of the Bureau out of reach of the miner to remove either its library or its mineral exhibit from the city; and as a miner, and as I believe expressing the views of the mauy thousand miners of the State, I protest against the removal of this our only school of instruction, and, if done, will arouse the indignation of this class of men who are the source of the prosperity of the country. Our views would be unmistakably expressed at the ballot box when the names of our representatives who vote for it come again before the people for their suffrage.

We as miners are entitled to recognition aud demand that our interests shall not be trifled with on this miserable plea of economy, when ten times the cost of sustaining the Mining Bureau can be saved in doing away with useless institutions that *are* useless. The Mining Bureau is not one of them.

San Francisco, Feb. 4, 1895. A Miner.

Mineral Resources and Industry of Corea.

Written for the Mining and Scientific Press by I. B. Storch, M. E.

Very few of our California miners are acquainted with the fact that Corea is a rich mineral country and waitiug for its development, which is but a question of time, pending on the conclusion of the present war. Rock salt, iron, copper, silver, gold and coal are the mineral resources discovered to date, but mining is limited to gold, gravel washing on small scale, and iron ore, while copper and tin are imported from Japan. Tin is used for coining and household utensils.

The Government taxes received from gravel mining are estimated to be about $15,000 per annum.

The mint of Corea was constructed by German engineers some time ago. It cousists of the latest modern aud complete machinery for coining silver dollars, but is not in operation—they seem to prefer the old primitive straw-covered institution, which is kept in full blast all the time coining the current "cashs" or "sapasks." The coin is round, $\frac{7}{16}$ to $\frac{13}{16}$ inch diameter, with a hole in its center $\frac{1}{16}$ to $\frac{5}{16}$ inch square, strung on a thread and worth about $\frac{1}{10}$ of our cent.

In the mouutain range Shanalin or Tshangpeshan, dividing Corea from Manchooria and running almost uorth and south through the whole peninsula, the prospector will meet with a rough climate between latitude 34° to 43° uorth. The southwesterly slope is favored with a fine climate, where semi-tropical products are raised, such as cotton, tobacco, rice, sesam, ricinos, black and chili pepper. The means of transportation in the iuterior are poor. There is only one wagon road from Seoul to the China line, used for ox carts; the commuuication with the rest of the country takes place by trails and pack animals. The interior trade is almost entirely in the hands of wandering peddlers.

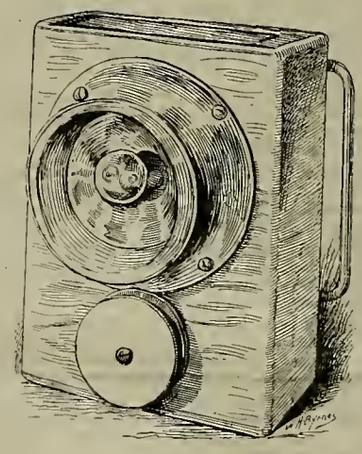
Manufacturing is yet in its infancy, except strawware and paper. The latter is of incomparable quality and made of hemp and wild silk. It is much superior to the Japanese fabricate. Fine and durable blanquetts, water-proof coats, umbrellas, etc., are made of this paper by saturatiug with oil.

Corea will open a great field to enterprising industry and mining within a short time.

Eureka Company's Portable Electric Lamp.

This lamp consists of an outside metal case, nickel plated and fitted with a switch on the handle.

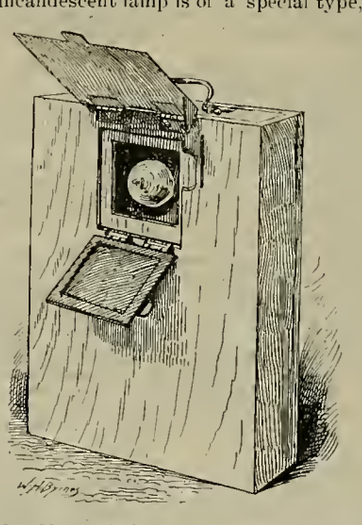
The battery is of the "Hough" type and gives an electro-motive force of six volts. The capacity (useful) in ampere hours is four. The cells are well



INCANDESCENT NIGHT LAMP.

sealed and fitted with hard rubber valves, which, although allowing the gas formed in changing the plates to escape, effectually prevent leakage of acid.

The incandescent lamp is of a special type, and is



PHOTOGRAPHERS' INCANDESCENT LAMP.

so construeted as to take a current of .5 ampere—which therefore gives a run of eight hours or thereabout.

The manufacturers issue a suitable primary battery which, with one charge of the chemicals, will recharge the lamp battery some tweuty or twenty-five times.

All wires and terminals are marked in such a manner that no mistake cau possibly happen in making the necessary connections between the lamp and primary battery.

The total production of copper in the United States in 1894 was 159,623 tons, against 142,480 tons iu 1893—a gain of twelve per cent. The total exports from this country in 1894 were 76,297 agaiust 80,392 tons in 1893.

The Refining of Gold Sulphides

Produced by the Precipitation of Gold from Chlorine or Bromine Solution with Sulphurous Acid and Hydrogen Sulphide.*

By WERNER LANGGUTH, Portland, Oregon.

Since the introduction of the improved method of precipitating gold from chlorine solution SO_2 and H_2S at the Golden Reward Chlorination Works, Deadwood, S. D., this modern method has been further adopted in the chlorination works of the Portland Consolidated Company at Deadwood, and in those of the Black Hills Mining and Smelting Company at Rapid City, S. D. It has proved practically most successful in the handling of large quantities of gold solution, and constitutes up to date, with Mr. John E. Rothwell's most important improvement — namely, barrel leaching under hydraulic pressure — the principal progress made in gold chlorination.

The method of refining the gold sulphides which result from this method of precipitation was introduced by me in 1890 at the Golden Reward Works, and in 1892 at those of the Black Hills Company. It has not suffered any changes during the last three years, and is substantially as described below:

The gold sulphides collected are dried already as far as practicable in the filter press by passing compressed air through them, and are then transferred (care being taken to avoid loss in handling) to light sheet-iron pans, twenty inches wide, thirty-six inches long and four inches high. Precipitate and filter cloth are kept separate as much as possible. If dried well in the press, the precipitate is easily detached from the filter cloth in pretty hard black-brown cakes. The pans, with precipitate and filter cloth, are now introduced into the muffles of the roasting furnace. In the latter plant, constructed by the writer in 1892 for the Black Hills Company, the roasting pans are two by four feet in area, with sides four inches high. The melting furnace is round, and three feet in diameter. At these works the dried precipitate and the filter cloth are transferred to the open cast-iron pans; the muffle is done away with, and the furnace is, in consequence, much simplified. Here the roasting gases escape by the telescope-shaped stack or gas catcher through the roof. The gas catcher is balanced by counter-weights. Its lower part is enlarged, and is lowered to about four inches from the top of the roasting pans as soon as the furnace has been charged, to allow sufficient free access of air from all sides. If the draft is too strong, the gas catcher is moved higher, and can thus be regulated to get the best condition for roasting. When the muffle or roasting pans are charged, the heat in the furnace is kept gentle at first to drive off the moisture, and is raised little by little to a dark red heat. Sulphur, arsenic and antimony are oxidized and driven off, and the filter cloth quickly burns to ashes when detached from the precipitate. The whole treatment of a charge can be conducted within two or three hours. The mass now invariably presents a red brown or yellow appearance, and only a very small percentage of arsenic and sulphur ought to be left. Some care has to be exercised, during the whole operation of roasting, not to lose any of the fine precipitate. The draft must be well regulated and stirring almost completely avoided. Steam drying before roasting is unnecessary, and only adds to cost and labor.

When sufficiently cooled, the roasted sulphides are carefully transferred by means of a hand scoop and brush from the muffle or the pans into the pulverizing drum, a cylindrical sheet-iron barrel, three feet in diameter and four feet long, running on trunnions, provided with an airtight manhole, and revolved by means of a crank or pulley. Some good-sized cobble stones put into it greatly assist pulverization. A little borax, soda and niter is now added, according to the composition of the sulphides. Sometimes the solution from leaching has not been quite clear, and a perceptible amount of slimes (ore) has accumulated with the sulphides in the precipitating tank; or the roasting before chlorination has not been as thorough as it might have been, and considerable quantities of arsenic and antimony have gone into solution with the gold in chlorination, and have been precipitated with SO_2 and H_2S, and not all eliminated in roasting the sulphides. All such circumstances have to be considered, and the necessary fluxes added, to secure a fusible slag of light specific gravity that will render possible the collection of the gold and a clear slag. If the ore treated in this mill is siliceous, the flux will have to be in general an alkaline one, such as soda, potash, etc. If, on the contrary, the ore is a basic one, a siliceous flux, such as glass or sand, etc., has to be added. If sulphur, arsenic or antimony has remained, niter or metallic iron may be added. Niter, however, must always be employed with caution, as it occasions violent action during fusion. As the conditions are always varying, the fluxing in each case has to be left to the discretion of the chemist or manipulator. The fluxes are added direct to the sulphides in the pulverizing drum, and become well mixed during pulverization. They should, at all times, be perfectly dry. Moisture in the flux, anywhere, will surely occasion loss during fusion, gold being carried away in the form of fine dust with the steam out of the crucible. Borax glass is to be recommended instead of common crystallized borax. The pulverizing drum has proved to be the very best machine for this purpose; since, if it is carefully closed, no dusting and consequent loss are experienced.

The gold is now metallic, being reduced by heat in roasting Au_2S_3 + heat = 2Au + 3S, and $3S + 6O = 3SO_2$. In melting the fluxed and roasted sulphides a crucible of good capacity, and yet easily handled, is of great importance. No. 100, Dixon's plumbago, has proved a suitable size. A little borax glass or slag is first put into the crucibles, each of which is filled to about two to four inches from the top, and a covering is given of borax glass or rich slag from previous meltings, which will prevent loss by dusting while the contents are fusing. The crucibles are now placed in the furnaces with the assistance of a pair of blocks and tackles and a basket tongs. A lid is placed on the crucible, and the steadily increasing temperature soon fuses the contents without any boiling or violent action. After fusion the heat has to be kept at very high temperature for some time to effect a complete collection of the smaller gold globules. The crucible is then taken out and quickly poured into a conical mold of suitable capacity.

The bullion separates from the slag in conical buttons. Each crucible melt of good sulphides produces from 100 to 150 ounces of bullion, from .800 to .950 fine. Arsenic, antimony, copper, platinum and silver are the principal impurities. The buttons are remelted, as usual, and cast into a bullion mold to be ready for shipment. The resulting slags are still comparatively rich in gold. They are crushed and pulverized, and the gold shots are panned out and added to the next melting. The tailings from this panning are dried and mixed with the slags of assays from the assay office, or other lead-containing substances. Metallic iron is added, and the mixture is melted in crucibles which have served for sulphide meltings a good many times already, but are considered not any longer quite as sound as is desired for this most important operation. The resulting lead bullion is cupelled, yielding the remainder of the gold. The slags resulting from this second melting are too poor to be rehandled.

The losses in refining by this method are almost entirely mechanical, and depend, therefore, to a great extent on the care and skill of the operator. The flue dust from the roasting as well as the melting furnaces has been assayed at different times after continued operations, but has shown comparatively little gold. There is, of course, some loss by volatilization in melting, but it is small, and only noticeable when arsenic or antimony is present in large quantity. I have once observed on the iron cover of the melting furnace a white sublimate of arsenic, which showed in some places a beautiful pink color. Some of this pink sublimate was carefully gathered and assayed, and proved to contain considerable gold. Experience has shown me that this loss only occurs at very high temperatures (above the melting point of gold) and in the presence of a large percentage of volatile metals, such as arsenic and antimony, and can be avoided altogether by careful roasting and fluxing.

The chemical fact that bromine dissolves and extracts gold from ores is in itself nothing new, but that several thousand tons of gold ore have been treated with technical as well as financial success, and the gold has been extracted not less easily—in fact, better and more cheaply—with bromine than with chlorine solution, is surely worth knowing. Last year the Asiatic cholera invaded Europe, and the price of chloride of lime advanced materially in consequence. I then employed bromine instead of chloride of lime and sulphuric acid, and practiced barrel bromination at the Black Hills Works in Rapid City, S. D. The cost of bromine was at first 35 cents per pound, but we received it later from the manufacturer on contract for 26 cents per pound. One to one and a half pounds was all that was needed per ton of ore that had been roasted fairly well. On well roasted ore less than one pound was quite sufficient. The outlay of 26 to 40 cents for bromine per ton of ore compared very favorably with 80 cents to $1 for chloride of lime and sulphuric acid; besides which, the handling was more convenient, and the extraction was from 50 cents to $1 better on ore that was not roasted as well as it ought to have been. We consequently changed altogether over to bromination. Thousands of tons have been brominated since, and I believe we have fully demonstrated, on a large scale, the technical and financial practicability of this branch of metallurgy. The methods of precipitation with the H_2S and SO_2, and the refining of the gold sulphides, as described above, worked as well on bromine solution as it had done before on chlorine solution, and made no changes of plant necessary.

*A paper read at the Virginia Beach meeting of the American Institute of Mining Engineers.

THE Anaconda, Montana, coal properties are soon to be put in operation. One hundred coke ovens are already finished and the coal washing plant is in operation and working well. Within a few days the ovens will be charged and the manufacture of coke commenced.

Arizona Gold Ores.

Dr. Theo. B. Comstock, in his capacity as director of the bureau of mines and geologist, has several tests of Arizona gold ores. He finds, as stated in his report to the board of regents of the university, that the Territory has three classes of such ores: (1) Those which are really "free" ores; (2) An intermediate class, partly "free" and partly "sulphuret;" and (3) The "sulphuret" ores. Many miners, who get colors in the pan or horn spoon and who afterward get good assays from their ore, are disappointed at the low percentage saved in the milling process. This is usually because they have overlooked fine-grained black sulphide which forms a considerable portion of the ore, although it may not be visible in the rock. Dr. Comstock is satisfied, from his investigations, that the working of gold ores in Arizona is yet in its initial stages, for there are deposits enough, rich enough and extensive enough to tempt the investment of capital, guided by thoughtful and economical engineering talent, when once the ores are understood.

THE use of malleable iron in car construction is spreading rapidly and railroad men are realizing that it is a material thoroughly adapted for that purpose. Nearly all of the castings employed in car work are used without any finish, and the smooth castings of uniform dimensions obtainable in malleable iron, and the greater strength, combined in most cases with a considerable saving in weight, makes this material particularly suitable for car construction. In 500 cars for which a Chicago firm has recently contracted, more malleable iron is employed than in any other cars thus far constructed. For some years past an important American line has employed malleable iron in the construction of its refrigerator cars, and the extensive use of malleable castings has been with this company a matter of several years' growth. On the cars just ordered, even the journal boxes are of malleable iron. A list of the parts which are cast in malleable iron, together with their weights, shows that there are nearly 1500 pounds of such iron in each car.

RECORDER SHIBELL, of Pima Co., Arizona, furnishes some figures on the working of mines by lead pencil done in 1894 through the exemption act of Congress, setting aside the requirements of $100 worth of work on each mine annually. During 1894 1200 mines in Pima county were exempted, the filing with the recorder being done on 300 blanks. These 300 notices cost $450 to file, and that was all the expense. Thus $450 did all what in other years would require $120,000 to do. On the 1200 mines thus recorded, work would have been done to the extent of at least $50,000. Many mine owners are well-to-do, and the poorer men, who would have done the work, are thus kept out of $50,000, in Pima county.

A NEW YORK PHYSICIAN writes to the *Electrical Review*, saying: "A watchman or janitor in the Thomson-Houston electric light station, 425 East Twenty-fourth street, New York city, a man about sixty years of age, recently told me that he had been for thirty years a sufferer from rheumatism. He had been employed in the electric light station, however, for the last three years, and for nearly all this time he had been free from rheumatism. He also stated that not a man in the station had rheumatism, and he considered the immunity due to the electricity."

THE first passenger steamer in the world to be lighted by electric lights was the Columbia, plying between here and the Columbia river. The first sailing vessel to be lighted by electricity is said to have been the Spanish bark La Vigusea, a bulk-oil and general cargo carrier. She is fitted throughout with incandescent lights, the power for the dynamo being furnished by a small oil engine, which also furnishes power to pump her oil cargo when she is loading or unloading.

WHAT is believed to be the biggest gas engine in the world is in operation at Pantin, France, where it drives a flour mill. It is capable of indicating 450 horse power, but the maximum load on it is only 280. It is operated with gas made on the premises, and the plant yields one horse power to each nine-tenths of a pound of coal consumed by the gas producer. Most steam engines require from one and one-half to three pounds of coal per horse power.

THE latest use for pulp is in the manufacture of paper pneumatic bicycle saddles. Bicycle mechanics have long since striven to invent an easier riding saddle for modern safeties. Well subdued pulp is compounded with certain ingredients and the saddle cast in parts. The two parts are the top and bottom, around the edges of which are ridges, which are lapped, sewed together and cemented.

THOUGH gold is not officially at a premium, gold refineries are now shipping gold bars to the East, and to brokers, instead of depositing in the mint, where, without any expense for expressage, they could get its coinage value.

Ore Production Without Profit.

In noting that meetings of prominent iron-ore producers have been held in Cleveland during the past few days to endeavor to arrange some plan of securing better prices next season, *Iron Ore* gives the following account of the financial results at several of the largest workings in the Lake Superior region during the past two years:

The big Minnesota Iron Company, with its vast stores of ore, its fine equipment and thorough systems, with its magnificent carriers on the lakes and its own railroad, has been unable to pay a single cent in dividends to its shareholders. For two years it has nothing to credit in the line of earnings, and those who have money invested in this giant corporation have received nothing therefor in the shape of earnings. The investment reaches well into the millions, and there must be a paying market in order to give return for these vast amounts. With all its many advantages, it has not been able to declare a dividend.

The Cleveland-Cliffs, with no royalties to pay, with abundant capital, with properties well located with reference to market, and with long experience in the business of mining, has failed to pay its shareholders a cent in the past two years.

The Lake Superior, with its fine possessions, cannot earn a dollar more than the cost of operating, and it has every advantage to carry on its affairs economically.

The big Tilden mine, of the Gogebic, is something like $500,000 in debt, and its affairs are in the hands of a receiver.

The Norrie finds no profit in the business, notwithstanding the fact that it sends out about a million of tons annually.

The Oliver, mining over half a million tons last year, lost anywhere from $20,000 to $75,000. Its ore was secured by steam shovel, and as cheaply as at any other Mesaba property. It is a royalty-payer.

The Chapin, the largest producer on the Menominee range, has been worked for several years without profit.

These concerns possess the most valuable properties in the different Lake Superior fields. The best machinery is employed in the working of the different mines. No other iron-ore producing region in the world is so progressive in this feature. Special attention has ever been given to a securing of the best, and calculated to cheapen the cost of mining. We secure our mine timber cheaply, explosives are very low, supplies of all kinds are reasonable, and still we are without profit.

Mexican Industrial Exposition.

An international exposition of industries and fine arts, authorized by the Federal Government of Mexico, by decree dated January 9, 1895, will be inaugurated in the city of Mexico on the 2d of April, 1896, and will remain open for a period of at least six months. This will be Mexico's first exposition, and will include all kinds of industrial, scientific, commercial and artistic productions.

The exposition will comprise a national and a foreign department, to which latter all nations may contribute, the Mexican Government granting the following privileges:

All goods and articles imported from abroad for the exposition will be treated by the Mexican Government as imported "in bond," and import duties will have to be paid only in case of sale. The materials and machinery for any buildings to be erected on the exposition grounds, or the entire buildings imported for erection there, are to be allowed to come in free of any duty.

The exhibitors and concessionaires—foreigners—those who sell foreign objects, or have shows in the foreign section, are exempt of all federal taxes.

The Mexican Government will use its influence with the railway and steamship companies to get the utmost facilities and the greatest possible reductions in the rates of freight on all goods and on rates of passage moneys for all persons connected with the exposition and visitors.

Those interested should address A. K. Coney, Consul-General of Mexico, 604 Clay street, San Francisco, California.

Edison's Forecasts.

Mr. Edison, in his speculations regarding the developments of the future, designates the greatest coming revolution to be that following on the yet unmade discovery how to generate electricity directly from coal. When science is able to do away with the intervention of steam boilers and engines in producing electrical energy, there will be a vast enlargement of the capabilities of electromotion, and an immense enhancement of the efficiency of coal as an industrial agency. It is worth noticing, adds an Eastern scientific journal, that the disposition to encourage a popular idea that electricity can relegate coal to uselessness is distinctly disavowed by Edison's view. Coal will remain the fuel of the future and the parent of all motion. Water may furnish some electric power; wind and sun power may do a little in addition, but coal will be the source of motion and power in the coming age. And the expansion of its utility in the manner suggested will increase its importance as an industrial factor. Beyond that, Mr. Edison thinks that the flying machine will come before long; that telegraphing between ships without wires is already practicable, and that new foods drawn from inorganic elements are among the possibilities. The first two developments will be anxiously awaited; but conservative mankind will be content to go on for a long time in the consolation that beefsteaks, fruits and other foods furnished by the chemistry of nature are good enough for this generation, if not for several of its successors.

Silver for Oriental Markets.

Several years ago, on his return from a trip around the world, the late ex-Governor Low, at that time one of the managers of the Anglo-California Bank of this city, was enthused over the possibility of diverting some of the silver intended for Oriental markets from London to San Francisco. It was known that England had enjoyed a monopoly of this trade for many years, even before silver became known as a product of any importance in the United States. Mr. Low expressed to the commercial editor of the *Bulletin* very decided opinions upon this subject, and requested of him a statement of the movements of silver from this port to those markets for a number of years. It was clearly demonstrated at the time that San Francisco had a natural right to handle a larger share of this trade than had been previously vouchsafed to her, in view of her proximity to the chief sources of supply in the Pacific States and Territories and Mexico, and her direct and frequent steam communication with the markets of consumption.

But Mr. Low found there were barriers to the realization of his hopes, first in the breaking of long established commercial relations with England, and also in the matter of charges. Though it was a more roundabout way of reaching the Oriental markets to send silver first to London and thence to India, China and Japan, than by way of San Francisco, it was found that the metal could be laid down there at less cost, or at least more satisfactorily, all things considered It is known that for many years the countries just named have been the largest consumers of silver in the world. Up to the stoppage of silver coinage in India, in June, 1893, that country was a particularly large absorber of silver, so much so that it had received the designation as the "Silver Sink" of the world. No one has ever been able to tell what has become of all the silver shipped to Oriental markets during the present century. For the past six years alone these shipments from England and San Francisco have been as follows:

1889	$57,654,712
1890	47,974,309
1891	41,379,445
1892	67,342,524
1893	67,715,485
1894	60,222,858

Here we have a total of $342,289,533 in six years, or nearly the total amount produced in this country, though much of the total was obtained from Mexico and other foreign sources. About 80 per cent of this silver was shipped from London, most of which was probably first sent from this country to England, thus leaving San Francisco only about 20 per cent of the trade. This unequal and unnatural condition of affairs was again recently brought to the attention of the parties interested, and a move was at once made to see if a remedy could not be found to bring about a more normal condition of affairs. California has little direct interest in the raw silver trade, because she has no strictly silver mines, but she has considerable capital invested in silver mines in adjoining States and Territories, and a direct interest in the smelting of silver ores and in the refining of crude and dore silver. It was found that if more of the silver intended for the Oriental markets could be shipped from San Francisco, it would be of much advantage to all concerned.

The chief obstacle lay in the matter of transportation expenses, including insurance and interest. These items of cost to the shipper by way of London were ascertained to a nicety, and then an appeal was made to the carriers by way of San Francisco. Wells, Fargo & Co.'s Express and the steamship lines out of this port were the parties consulted, and they met the demands of shippers and refiners in a friendly spirit. Without going further into the particulars, it may be stated that silver bullion can now be sent to Japan and China from Colorado and intermediate points on more favorable terms to the producers than by way of New York and London. The new arrangement has been in operation only a few months, but is being patronized by some of the largest producers at Denver and Pueblo, Colorado, and also at Omaha, although from the latter place only fine silver has been received for shipment. Colorado, on the other hand, is sending fair quantities of crude silver, which is refined here, thus giving us the benefit of that part of the work and the gold that is extracted from the same. Great credit is due to the parties who have combined to bring about this change. The silver shipments from San Francisco to the Orient since 1875 have been as follows:

	Silver Bars.	Mex. Dollars
1875	$281,273	$1,820,647
1876	2,537,286	2,848,447
1877	5,562,123	2,619,527
1878	8,048,485	2,189,070
1879	5,908,819	2,347,911
1880	2,401,259	2,211,574
1881	2,530,542	2,205,459
1882	3,017,290	2,399,930
1883	5,505,578	4,197,370
1884	5,993,678	8,049,496
1885	7,489,091	9,934,058
1886	7,700,771	9,230,725
1887	8,049,465	6,292,779
1888	7,902,700	5,641,328
1889	8,627,252	9,894,712
1890	302,300	6,812,997
1891	583,219	7,105,806
1892	3,020,450	10,569,945
1893	2,511,956	9,281,760
1894	7,210,950	5,369,891
Totals	$97,164,489	$111,923,432

In addition to the fine silver and Mexican dollars, as above set forth, there was also shipped from January 1, 1875, to December 31, 1889, the sum of $20,340,344 in trade dollars, made expressly for this trade at the United States Mint in this city. All but $18,550 of these dollars were shipped from 1875 to 1879 inclusive. The trade dollar was authorized in February, 1873, and the shipments hence in 1873 and 1874 were $5,406,969, so that altogether these shipments amounted to $25,747,313.

The movement of silver from Colorado to China and Japan by way of San Francisco began in the last half of 1894. The total cost of shipping $1000 in fine silver from Omaha or Kansas City to Hongkong via New York and London is $17.31 and from Denver $19.06, while to Yokohama the charges are $18.81 and $20.56 respectively. These figures include interest and insurance. The cost by way of San Francisco to Hongkong is $14 from Omaha and Kansas City and $12.50 from Denver and to Yokohama $13.50 and $12.50 respectively. Through bills of lading from Colorado to Japan and China, with stop-over privileges at San Francisco, are allowed on all silver that needs to be refined here.

A Protest.

The miners are entering a vigorous protest against the removal of the State Mining Bureau, and here in Nevada City the following memorial to the Legislature is being circulated and numerously signed:

"We, the undersigned, interested in mining in Nevada City, Nevada county, enter a vigorous protest against the abolition of the State Mining Bureau, or its transfer to the State University.

"The Mining Bureau is the only State institution maintained in the interests of the miners of California, and is doing useful and satisfactory work. It should be continued as it is and a liberal appropriation given, to still further help the mining interests of California, which need fostering just as much as those of an agricultural nature."—Nevada City Herald.

A similar protest is being circulated and signed in every mining county in the State.

Messrs. T. D. F. Andrews & Co., of London, England, have made some experiments upon the inductance of sheathed cables. The results show that, whether the sheath or outer concentric covering be of iron or copper, the inductance is practically the same; and if an ordinary copper concentric cable be used in place of the iron armored cable of the same cross-section, the results are the same in every case. This is interesting so far as it goes, but a little information regarding the periodicity at which the tests were made would add to the value of these observations.

The Plata Reina Mining Co., an American company, which operated the Pancha de Plata mine at Sonora, having lost possession by neglect to comply with the Mexican mining laws, it was "denounced" and operated by Ignacio A. Pesuira and associates, who have been successful, having extracted and shipped 600 to 800 tons of silver ore, worth $200 per ton. The Plata Reina Mining Co. are endeavoring to get the Mexican Secretary of the Interior to dispossess Senor Pesquira and award them the property.

The Debris Commission have issued hydraulic-mining permits to the Kentucky Flat Company of El Dorado county, and the New York Mining Company and the Dutra Wilder Company of Yuba county.

The Lady Emma Mining Company has incorporated in this city. Capital stock, $100,000. C. E. Brown, W. B. Roberts, M. Otey, W. H. Hamilton, N. L. Beel are directors.

A five-cent stamp now will carry a letter to any country in the world that maintains postoffices.

The Jackson, Sonoma Co., mine produced 128 flasks of quicksilver in January.

Gold Mining in California.

Discoursing of gold mining in this State, Geo. Partridge writes to the Denver *Mining Record* as follows:

There is every symptom of a great revival of mining in California. The little village of Jackson, in Amador county, which has been in a comatose condition for years, has now scarcely room for the newcomers, and Coulterville, in Mariposa, since the advent of the Boston and Montana Company, which is resurrecting the famous Cook property, is putting on airs, and talks of $400 a front foot for village lots. Prospectors are also talking many thousands for their claims all along the belt; similar activity toward it came too late to affect last year's output, but will no doubt largely increase the output of 1895.

It may be truly said that our mountains have been scarcely more than scratched, and it can be said also that failures to succeed, when they occurred, have been from reasons that would have broken any business in the world. The quartz is here in great abundance, but it takes good mining and good honest will to turn it into gold. It is quite as much a question of will as of quartz. We consider $8 ore, with a three to four foot ledge, a good bank to draw on, yet many ledges go higher as well as lower. There are some twenty to thirty feet wide that mill $3 to $4, and some that are of greater width that yield $2 a ton, and such veins have been worked a long time at a cost of fifty cents a ton for mining and milling. The ore is soft and broken and forty tons is put through a ten-ton roller mill. With the large ledges of $3 to $4 rock a large mill is the factor of success. The Utica mine of Hayward & Hobart at Angel's Camp began with $3 ore, but it got better, and with 240 stamps now yields about $160,000 monthly.

The Kennedy mine, in Amador, nets about $50,000 monthly, with 30 stamps. There are thousands of five and ten stamp mills in the State, but as all are in private hands and close corporations little can be learned of individual profits. No gold mines are listed on our stock exchange. The ground cost of mining and milling in "going" mines is but $3.50 per ton. Many a mine would pay all cost of development from the grass roots with a little two-stamp mill that costs here but $500 without power, and mills five to six tons daily. The prospector needs about $1500 to set up such a mill, and there's the rub.

About five years ago a miner offered a mine he had bonded and put a five-stamp mill on at an inconvenient distance, so that he could only about meet expenses from an eight-foot ledge of $8 quartz. He was in debt and offered to sell for $25,000, but he could get no buyer. So he pegged away, and in two years he had twenty stamps and a monthly income of $8000 net; then capitalists wanted to give him $200,000 for it, but he concluded it was worth that to keep.

This suggests the apparent mistake that capitalists make in trying to buy a paying proposition at a big price, based on its current output and what is in sight. The late George Hearst used to tell the boys: "I'll give you what you have in sight and take my chances on the rest for profit," but estimates generally disagreed. When a mine is equipped with a mill the owner is independent, and as a prominent expert here says, asks a price that will pay about four per cent on the investment. When he has no mill he is on his knees and the buyer can purchase and equip for a fraction of what the equipped mine would cost.

The mountains are full of partially developed prospects that can be had for a pittance in comparison, with safe evidence of a good ledge. Half-interests are plentiful for a mill and working capital, and an option for a year on the other half.

The free-milling character of all our ores makes milling cheap. Gold is saved over concentrators at a cost of about $1 per ton. Mining is safe for a good profit with a three-foot ledge of $5 ore. Tunnel mines give the minimum for mining expense, of course, but our deepest shaft mines require no costly pumps to keep down the water. It seems foolish for miners to go to Africa or Coolgardie with the best of conditions at home, and only a few days' ride from the city; but distance lends enchantment. Some of our capitalists have worked in Mexico, but with poor returns, with a few notable exceptions. A brilliant success has lately been achieved in Lower California, forty miles inland from the Pacific coast. With ten stamps $125,000 was made last year, and twenty more stamps are now being placed. The grade of ore is over $100, and there is enough in sight for years. It has been developed 400 feet. A prospector has recently located sixteen claims in another locality, showing outcrop from three to forty feet wide that mills from $20 to $30, and offers half for working capital. There is little silver in California; she therefore cares little what becomes of silver, though nine-tenths of the people favor giving silver the old chance at free coinage. The diversion of mining in Colorado to gold will make many of your people lukewarm about silver ere long, but after all the agony over gold, what is the aggregate gain? In a year there is about as much produced as goes abroad in a few days, and the goldbugs think that the single standard can be sustained on this.

AFTER a session of ten days the coroner's inquest into the causes of the terrible explosion in Butte has resulted in a verdict charging that the deaths caused by that dire event were due to the explosions of dynamite in the warehouses of the Kenyon-Connell Commercial Company and the Butte Hardware Company; that the fire started in the Kenyon-Connell warehouse; that the first large explosion occurred there; that the second large explosion took place in the Butte Hardware Company's warehouse; that the two companies have been criminally negligent and careless in carrying in their warehouses quantities of powder in excess of the amount allowed by law, and that the two companies are responsible for the deaths of the victims of the explosion.

WE ARE IN RECEIPT of the report of Messrs. Grunsky & Manson, consulting engineers, with accompanying maps, regarding the proposed system of drainage and protection works for the valley of the Sacramento. It is comprehensive and feasible. The report estimates a total cost of $9,287,000. While this appears a large amount, it must be remembered that the expenditure would furnish drainage and permanent protection to a region that has already unsatisfactorily expended $17,000,000 for similar purposes. The report is an exhaustive one and is the result of the steady detail work of over a year.

PLACER

Amalgamators, : Dredgers, : Shovels.

Complete "Lancaster" Gold Amalgamating, Concentrating and Hoisting plants furnished for treating large quantities of low grade placer ground at a small cost with minimum supply of water or compressed air. **Highest possible Gold yield insured.**

Outfits include "Lancaster" 1895 Land or River Dredges, Grapples, Scoops, Steam Shovels and Cableways of the most approved construction. Success guaranteed. Capacity, one hundred tons hourly and upward, if required. **Crushing, Pulverizing, Concentrating and other machinery also built.** Investigation solicited.

JAMES H. LANCASTER, Patentee, 39 Cortlandt St., NEW YORK.

PLACER AMALGAMATORS

Combined with Steam Shovel or Dredge.

BUCYRUS SYSTEM.

NEW METHOD OF PLACER MINING.

Saves all the Gold. Uses very little Water. Treats large quantities at Low Cost

Built solely by the

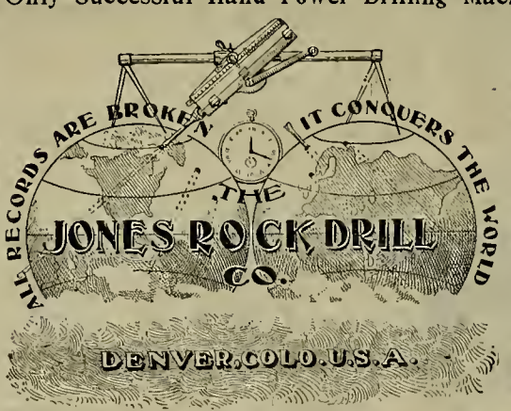
BUCYRUS STEAM SHOVEL AND DREDGE COMPANY,

South Milwaukee, Wis., U. S. A.

THE JONES ROCK DRILL

IS THE

Only Successful Hand Power Drilling Machine Ever Invented.



It is strong, durable, reliable, simple, compact, light, easily handled and operated by one man, and will reduce the cost of rock drilling at least Fifty per cent.

Our handsomely illustrated pocket catalogue fully explains the features and workings of the drill. It should be in the hands of every mine owner, leaser, contractor and prospector in the West. *Sent free on application.*

If you are interested in Rock Drilling Correspond with us.

WE CAN SAVE YOU MONEY.

MINE BELL SIGNALS.

Adopted, Used and In Force in Accordance with State Law.

FOR THE CONVENIENCE OF OUR READERS IN THE MINING COUNTIES WE PRINT IN LEGAL SIZE, 12 X 36 INCHES, THE MINE BELL SIGNALS AND RULES PROVIDED FOR IN the Voorhies Act, passed by the State Legislature and approved March 8, 1893. The law is entitled "An Act to Establish a Uniform System of Mine Bell Signals to Be Used in All Mines Operated in the State of California, for the Protection of Miners." We can furnish these Signals and Rules, printed on cloth so as to withstand dampness, for 50 cents a copy. MINING AND SCIENTIFIC PRESS, 220 Market Street, San Francisco, Cal.

The Mineral Hydrocarbons.

Their History, Geography, Geology, Physical and Chemical Properties and Uses.

NUMBER XXI.

1880.—There were produced 40,552 barrels of crude oil in 1880, bringing the total yield up to 275,637 barrels.

1881.—Oil produced in the State this year amounted to 99,862 barrels; total to date, 375,499 barrels.

A. C. Dietz & Co. established the Berkeley Lubricating Oil Works for the manufacture of lubricating oil from California material, brought from Ventura county. He turned out 100 barrels per day, so published. In February there were seven new wells being drilled in the State, and the last year's output was doubled. The oil business in California was at that time of greater magnitude than was generally known. Citizens of Los Angeles, Ventura and Santa Barbara counties signed a petition asking the United States Government to instruct Clarence King, then Government Geologist, to make special surveys of the oil regions and to note the development since 1865. They represented that a belt of oil shale extended for eighty miles in length, from the San Fernando district in Los Angeles county through Sespe, Santa Paula, Ojai and Sulphur mountain in Ventura county and the Carpinteria and Santa Barbara districts, terminating in the Pacific ocean at Goleta, in Santa Barbara county; that though the indications were encouraging, yet the work had been done somewhat blindly and without scientific guidance. Much money had for this reason been lost—believed to be as much as $1,000,000—with unsatisfactory results. Practical oil men and capitalists familiar with the subject were of the opinion that the results of their work indicated that a large quantity of petroleum of good quality existed, but they feared to progress without scientific investigation. In consideration of the importance to the whole country of the vast interests involved, they felt that they had a right to ask aid from the General Government.

1882.—Oil produced in the State, 128,636 barrels; total to date, 504,135 barrels.

1883.—Oil yield of the State, 142,857 barrels; total production to date, 646,992 barrels.

1884.—Maltha and crude brea were known in San Luis Obispo county in 1874; in 1884 samples of each were brought to the State Mining Bureau, also from Steele's ranch, which were described as rising from a natural well 100 feet deep "from which it overflowed and became solid asphaltum." This specimen is marked No. 5058 in the museum catalogue.

In 1884 the annual production and consumption of asphaltum in the State was estimated at 3500 tons, and the price in San Francisco was from $9 to $11 per ton, according to quality.

Mr. Lyman Stewart, of the firm of Harrison & Stewart, stated to me that the Pennsylvania company, of which he was a member, had invested in Pico canyon and elsewhere in Los Angeles and other counties $130,000, a large portion of which was a loss. They sauk six wells in Pico canyon and one in Sauta Paula, all of which were "dry holes." Mr. Stewart came to California from Titusville, Pennsylvania. He brought out thirty men, all of whom were skilled workmen. Some of the wells sunk by them were deep. He said if he could obtain one well the company would soon make up the loss. They were then drilling in Pico canyon near the Pico well.

On the 19th of September the Ventura *Free Press* published the followiug: "At last the long-looked for oil began to flow through the pipe line from Santa Paula; the pure oil began to flow yesterday at two o'clock."

The Pacific Coast Oil Company produced twelve barrels of crude oil daily from the Santa Cruz mountaius, eighteen miles from San Jose, and from ten to twelve barrels daily from near Pescadero, San Mateo county. Crude oil was largely used for making steam in various parts of the State.

The San Fernando district produced 625 barrels and the Ventura wells 700 barrels daily for a portion of the year. The total yield for the State for the year was 262,000 barrels and the graud total to date 908,992 barrels.

1885.—During this year companies were organized and were prospecting for oil in Alameda and San Mateo counties. The State production of oil was 325,000 barrels, making the total to date 1,233,992 barrels.

1886.—There was considerable prospecting for oil during this year. Crude petroleum was largely used in Los Angeles, Santa Monica, Pasadena, Monrovia, Santa Ana and other towns. It was fouud to possess all the requirements for fuel in numerous manufacturing establishments iu southern California. At Los Angeles the monthly cousumption was said to be 3000 barrels; some large establishments required as much as 500 barrels monthly. The price per barrel was about $2.31.

At Sycamore Grove, near San Louis Obispo, A. Walker, F. Adams and Dr. G. R. Nichols commenced sinking a well for oil. At 936 feet hot sulphur water rose, holding in mechanical suspension a considerable quantity of natural gas, much like the wells in Stockton. All hope of obtaining oil being abaudoned, and the water flowing in abundance, a health resort was established, which met with encouragement. It is now known as the "Sycamore Hot Sulphur Springs." The water has a temperature of 103° F. and a distinctly mineral taste. It is situated on the railroad, about seven miles from San Luis Obispo and three from Port Harford. I visited the locality in May, 1893.

Sespe canyon is credited with the yield of 700 barrels of oil daily, Newhall with 450, Puente with 100, and other districts with 50—a total of 1300 per day. This is evidently an overestimate, for the production of the State for 1886 was but 377,145 barrels, instead of 474,500 by the first-stated estimate.

The total State production to this date was 1,611,137 barrels.

1887.—The largest producing oil well in the State, situated six miles from Santa Paula, Ventura county, flowed for a time 600 barrels daily without pumping. Several pumping wells in the same neighborhood produced from 100 to 200 barrels per day.

There was much prospecting during this year but no new districts were discovered. Crude oil was more largely used in San Francisco, and the consumption in the southern part of the State continued. Three barrels of crude oil were cousidered equivalent to one ton of the best steam coal. The New Almaden quicksilver mine and Clark's potteries in Alameda used it for making steam. The Pacific Gas Improvement Company used seventy-five barrels daily in making gas. The San Francisco and the Los Angeles gas companies altered their plants, or were about to do so, that oil might be substituted for the more expensive coal in the manufacture of illuminating gas.

Crude petroleum of California production was sold in carload lots for $1.50 to $1.75 per barrel, and there was au increased demaud for the uew fuel in the State.

A new refinery was being built in Santa Paula, Ventura county, and Newhall oil, refined at Alameda Point, began to be considered the best illuminating oil produced in the State.

The chief producing counties were Los Angeles, Ventura and Santa Clara. The annual yield had increased to 678,572 barrels, and the total State production to that date was 2,289,709 barrels.

Bituminous rock in large quautity was discovered on the Coral de Piedra ranch, six miles south of San Luis Obispo, in January, by Mr. James Cormack. During the year 3600 tons were extracted and sold. The San Luis Obispo Bituminous Rock Company was incorporated.

1888.—During this year, by uewspaper accounts, twelve counties in California produced oil, as follows: Alameda, Colusa, Humboldt, Los Angeles (420,000 barrels), Monterey, San Benito, San Luis Obispo, San Mateo, Santa Barbara, Santa Clara, Santa Cruz and Ventura (237,000 barrels). This probably includes asphaltum as well as petroleum.

By this estimate Los Angeles and Ventura countics produced jointly 657,000 barrels. United States statistics credit the State with 690,333 barrels, leaving 33,333 or its equivalent to be divided between the other counties mentioned. The total product of California, including this year, was 2,980,042 barrels. The principal oil-producing wells were at Puente and Pico, Los Angeles county, and at Sespe, in Ventura county.

In December, in Adams canyon, Sespe, a well being drilled spouted oil seventy feet high, from a reservoir tapped by the drill 700 or 800 feet below the surface; the well began to yield at the rate of 800 barrels per day. Two wells in San Mateo county each yielded a small quantity of oil.

A San Francisco newspaper published the following:

AN OIL FLOW.—A Los Angeles paper says: Reports from a most reliable source reach this city to the effect that the oil horers in Adams canyon, in the Sespe country, Ventura county, have struck it rich. The flow, as Dame Rumor represents, equals 1100 barrels a day for the last well sunk. It is said, moreover, that the well is capped, as well as they can cap it, to keep the oil from flowing in even larger measure. As it is, there is no means at hand to take care of such a Pactolean stream and this richness is running wild all over the country. They are leading it into all sorts of natural receptacles to prevent an oleaginous flood. If this is true, as it most likely is, the good news is of the highest importance to this section.

The Union well, at Buena Vista, Kern county, one and a half miles from the Columbia, was drilled in 1888 or 1889. At 720 feet, while driving a pipe, a series of pulsations began, which caused an eruption of rocks and an escape of gas, "which raged aud roared for half a day." This statement was made to me by Mr. Hambleton, who was there at the time. Some of the stoncs ejected might have weighed five pounds. Considered as ruined, the well was abandoued. Mr. W. E. Youle, who was superiutendent in 1889, thinks this phenomenon was caused by the rising of water iu the pipe, and not by gas. He has had a similar experience. He thinks that if the eruption had been caused by gas, it should have occurred while the tools were still penetrating the earth at the bottom of the well. On the other hand, a person considering the matter would be loath to admit that a rise of water could produce a sufficieut rush of gas to eject stones, or would have continued for half a day, "with a roaring sound, as described. Mr. Hambleton was quitc convinced that there was a genuine escape of gas.

Deposits of gas were discovered in Canyon Diablo, Sau Miguellito, the property of the Ventura Asphalt Company.

A large deposit of bituminous rock—so called — was discovered in Santa Cruz county during the winter.

1889.—The yield for this year was 30,220 barrels, making a total of 3,283,262 barrels produced so far in the State.

(To be Continued.)

To Operate California Mines.

The Nebraska Gold Mining Company filed articles of incorporation. Its capital stock is fixed at $500,000, divided into 25,000 shares of the par value of $20 each. The officers aud incorporators are Henry W. Browu, president; John Heimrich, vice-president; John Dern, treasurer; E. H. Aires, secretary, and William S. Brown, the same persons constituting the board of directors, and all of Salt Lake City excepting John Heimrich and William S. Brown, who are residents of Nebraska. The property of the company is described as the Ohio and Mouutain Lion Mining claims, situated in Cottonwood mining district, Siskiyou county, California. The general offices of the company are located at Salt Lake City.—Salt Lake Tribune.

Mechanical Progress.

The Simplon Tunnel.

At a recent meeting of the Pacific Coast Technical Society, at their rooms in the Academy of Sciences, some interesting notes were read on the great tunnel under the Simplon between Switzerland and Italy. This will, when completed, be the longest tunnel in the world—12¼ miles, as against 9½ miles for the St. Gothard, nearly 8 miles for the Mount Cenis and 4¼ miles for the Hoosac. As proposed by the report of engineers in charge of the preliminary work, the two tracks will not be carried in a single large tunnel, but in two smaller parallel ones, 58 feet apart between centers, and connected every 660 feet by crosscuts. The average area of the section of each of the tunnels is to be about 250 square feet, the width 16 feet 5 inches and the height 18 feet. The plans of the contractors are explained at length in a recent issue of the organ of the Swiss Engineers' Society, and are quite different from the methods generally adopted heretofore. As the contract calls for the completion of one of the tunnels and the construction of a working gallery along the line of the second as the first portion of the undertaking, the contractors, Brandt, Brandau & Co., of Hamburg, have decided to drive two galleries from each end as the basis of the two tunnels and to connect these every 660 feet by the crosscuts, which the contract calls for. One gallery will be enlarged immediately to the full cross section to form tunnel I, while tunnel II will be completed only when the first no longer suffices for the traffic. The clear section of gallery II will be used for ventilation, and as it has an area of 86 square feet, it is believed to be ample for the purpose. Its entrance will be closed by doors and air will be blown into it by powerful fans. The crosscuts are to be closed, except the two end ones, so that the air must pass in through gallery II and out through gallery I, thus maintaining a current which is expected to ventilate the workings sufficiently. The material excavated in tunnel I is to be taken out through the same tunnel in traius drawn by steam engines, which will go back to the workings through gallery II and the crosscuts. Both galleries will be driven by Brandt hydraulic drills, three or four at each heading, and it is expected that the progress made with them will be at the rate of 19 feet a day. Recent improvements in the drills have materially shortened the time required to make the holes for one blast, and the efficiency of the latter is increased by reason of improvements in explosives. The contractors also expect to make a considerable saving of time by throwing the blasted rock backward with hydraulic power at the moment of the explosion. Thus the rock, instead of lying within a few feet of the face, is scattered back for some distance, and the drills can be set up again in a shorter time. The tracks laid for carrying rock and supplies in and out of the galleries are connected through each crosscut, and have a gauge of 2 feet 7½ inches. The air for ventilation is to be forced into the tunnels by two 18-foot fans at each portal, and a number of devices are to be employed to make the progress of the air through the workings conform to the plan laid out. For doing this work the contractors are to receive the sum of $9,040,000 when the tunnel I and the gallery II are complete, and if this part of the undertaking is not completed in 5½ years, they are to be fined $1000 a day for the remainder of the working period. There is a previous payment of $1,251,000 when the power plant and other apparatus for working are set up, but the large payments are not due until the first tunnel is ready for regular traffic.

Now that photographs are taken of the underground workings of mines, the proposition of Professor Glusmatt to use aluminum powder, instead of magnesium wire, for producing the necessary light will be found of interest, especially as aluminum is far cheaper than magnesium. The mixture recommended is the following: Aluminum powder, 21.7 per cent; sulphate of antimony, 13.8 per cent, and chlorate of potash, 64.5 per cent. The combustion of this powder, in effecting which great precaution is necessary, is excessively rapid—only one-seventeenth of a second; but the duration may be increased to one-fifth of a second by mixing thirty parts of aluminum powder with seventy of chlorate of potash.

Machinery in Business.

"The desk of a business man nowadays is quite a mass of machinery," says the manager of a firm of engineers to a representative of *Machinery*. "Just look at this one of mine, for example. To begin with, here is a phonograph, into which I dictate all my letters. Afterwards a young woman, who acts as my amanuensis, takes the cylinders and copies them off. For communication otherwise than by writing, I have at my hand a small stand which supports a telephone. It is ornamental and movable. I put it out of the way or set it in front of me, according to my convenience. With this little instrument I can talk from my desk with all the world. It is a long-distance telephone, and with it I can call up Paris as well as Liverpool. Besides, I have at my other elbow a similar contrivance for communicating with the various rooms under my superintendence in this building. At a moment's notice I can make connection with any one of them by sticking the plug into the proper place in this circuit board. My desk is a center to which ever so many wires run for a score of different purposes. Some of them furnish me with electric lights, others give power to my electric fan. Overhead you notice a clock, which at noon every day is corrected by electricity from the Royal Observatory. My office is a nest of machines and wires, the latter reaching out to the uttermost ends of the earth. For, by means of this telegraph sounder at my left hand, I can transmit intelligence to America, to India, to New Zealand or to Hongkong. It is not without reason that this is called the age of mechanical civilization."

A 320-H. P. Gas Engine.

The flour mills of M. Leblanc, at Pantin, France, have been provided with a 320-horse power fuel-gas engine of the Simplex type. The machinery and gas generators are arranged for continuous working, day and night. The gas is washed and scrubbed and run into a gas holder. There is no india rubber in the apparatus. With coal gas the machine gives 450-horse power. There is one cylinder, 34.8 inches in diameter; the piston stroke is 40 inches, and the speed 100 revolutions per minute. Special arrangements have had to be devised in order to keep the different parts of the machine at appropriate temperatures. The coal used is 0.812 lb. per indicated, or 1.03 lb. per brake horse power. The water used is 8¾ gallons per brake horse power per hour. After a three-months' run the tests were repeated and then gave even more favorable results. Everything is done by machinery in these mills, and the gas engine also runs the pumps and 300 glow lamps. The consumption of coal is remarkably small as compared with that of steam engines of the same power. Anthracite is unnecessary, for the new generators devised by the Buire-Lencauchez need only poor coal, at half the price of anthracite. Better coal yields too much tar, which is difficult to deal with; and the problem of the future is to use small coal and coal dust.

Gas Motor on Shipboard.

A novel method of using coal gas in navigation has been successfully tried at Havre, France, for a syndicate of capitalists. An iron boat of 350 tons was built, a vertical gas motor of forty H. P. furnishing the power. Coal gas compressed to a pressure of 1400 pounds per square inch is stored in steel tubes placed between decks, and a regulator situated between the gas reservoir and the motor reduces the pressure of the gas entering the motor to the flow ordinarily required. Trials have been made with this boat in presence of the mayor of Havre and the harbor officials, and the result was absolutely conclusive. This new boat, christened L'Idee (The Idea), has been over the course from Harfleur to Rouen and behaved perfectly. It was a source of wonder to all to see her wending her way among the large vessels in port at full speed without noise and without smoke. The captain has full control over his vessel from the bridge. He can change her course, slacken or increase her speed, and stop or even go backward almost instantaneously, thanks to the reversible screw. Before long a flotilla of sixty similar boats will perform a regular service between Paris and Havre and Paris and Creil. Gas works are building along these routes, and will supply the gas according to the needs of the service. The cost of power will be more economical than any other, but the chief saving will be effected in the comparatively small room taken up by the motor, allowing considerable more freight to be taken in. A remarkable fact, worthy of notice, is that pure coal gas, compressed to a pressure of as high as 2000 pounds per square inch, does not show an appreciable condensation.

Pipe Bending.

Small iron pipes, up to one inch in diameter, may be bent cold and even coiled by winding them around a mandrel in a lathe, provided the diameter of the coil is at least nine or ten times the diameter of the pipe to be bent. Short bends in iron, brass and lead pipes are apt to flatten at the bend. This is frequently prevented by filling the pipe with lead, which must be melted out after the bending has been completed. A set of "bending coils" can be easily made by any machinist for use when occasion demands. A separate coil is needed for each size of pipe to be operated upon. Steel wire is wound into a coil, which will slide easily inside of the pipe to be bent. One end of the coil should be tapered to allow it to enter the pipe easily. The other end ought to be fitted with an eye turned in the end of the wire. Into this eye a cord or chain must be fastened, so the coil may be pulled out of the pipe after bending. The pulling out of the coil does not require as much power, after the bending, as would be supposed, because the pulling of the coil lengthwise causes a decrease in the diameter of the coil, which permits it to be drawn easily out of the bent pipe. Wire one-eighth of an inch in diameter should be used for a bending coil for a pipe one inch in diameter; for one and one-half inch pipes, one-quarter inch should be used.

THE most powerful dynamo ever constructed in the world has been shipped to the Niagara Falls Power Company and the Cataract Construction Company. This mammoth electrical generator is one of three to be attached to the monster 5000-horse power turbines built and placed in the wheel pits of the power company.

JUDGE GROSSCUP, in the U. S. Circuit Court at Chicago, has declared the Thomson-Houston Regulator patent invalid.

20-Stamp Mill for Sale.

In Southern California, a 20-stamp Gold Quartz Mill, with engine, boiler, self-feeders, rock-breaker, etc.

As the premises are adjacent to Railroad, the Mill could be conveniently removed. Can be had at low price for cash. Address: "Quartz Mill," care MINING AND SCIENTIFIC PRESS, San Francisco.

FOR SALE.

1 Latest Improved Bruckner Furnace.
2 Chlorinating Cylinders of cast iron, lead lined.
1 set Krom Rolls.

The above in use but a short time. For sale cheap. Address L. C. S., Box A., Mining and Scientific Press Office, S. F.

Founded by Mathew Carey, 1785.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

MINING ITEMS.—*Record:* Sonth Eureka—The contract for sinking the shaft 150 feet deeper, more or less, was let last Monday. There were about twenty bids received. The following-named persons constitute the crew to whom the contract was awarded, they being the lowest bidders: John A. Bennetts, Nick Balcovich, S. H. Hoskins, John Chenoweth, James Dahh, Amos Treloar, Thomas Trevana, John Rodda, John Marchetti. The contract price is $11 per foot, contractors to furnish powder, candles, caps and fuse. While this is considered a low figure, it is claimed that they can make small wages—from $2.25 to $2.50 per day. The shaft is down 900 feet, and this sinking will carry it to about 1050 feet. The total cost of sinking to the company will exceed $20 per foot. It is pleasing to be able to state that the prospects are flattering that the South Eureka will prove one of the best paying mines in the county in a year or two. One level at 750 feet has been opened, showing a fine ore body. It is the intention to open up another level at a great depth, and this developmeut is expected to be equal to keep a mill running steadily. It is the intention to erect a mill this spring, of what capacity we have not heard.

KENNEDY.—This mine continues to yield its usual generous quantity of the precious metal monthly. Notwithstanding the heavy flow of water, consequent upon the unusually heavy rainfall, no difficulty has been experienced in handling it, thanks to the existence of two working shafts. The lowest drift is at the 1750 foot level, hut no stoping has been done there as yet, and it is not probable that any will he done for a year or more yet. A station has been cnt at the 1850 level. The south shaft is down 1950 feet and the north shaft is now being snnk to the same depth.

MISCELLANEOUS.—The steam whistle of the Anita mine was heard for the first time this week. This makes five mine whistles within hearing of Jackson, namely, Kennedy, Zeile, Alma, Argonant, and Anita. The draining of the Anita shaft is in progress, and sinking will he resumed in a few days.

The water in the Zeile shaft has slacked up since the heavy rains ceased. It is still very strong, however, requiring the constant activity of the pumps to control it. The repairing of the shaft bas reached the 700 level, about one-third of the entire distance. It will he two months before mining can he resumed.

J. Benardis is operating the Maximillian quartz claim, near Sutter Creek. He keeps a three-stamp mill at work, and is feeling his way cautiously to a higger venture. The property is on the east vein of the motber lode—low grade rock, hut vast quautities of it.

The case of Amador Gold Mine vs. Amador Gold Mine Limited, is on appeal before the Supreme Court. The transcript on appeal was filed in the higher court last week.

Pipe laying to convey water from the Oneida Hill to the Argonaut mine was resumed last week.

Inyo.

At Mountain Spring, on the east side of Salt Wells valley, on the old Darwiu stage road, about twenty miles from Indian Wells, there are about fifty men in the new camp and more are going there. There has also been a revival of the old mines about fifteen miles west of the stage station at Red Rock. These mines were worked many years ago and abandoned. The old tunnels bave been cleared out and good strikes of ore are reported. F. Fitzgerald and W. Smith have struck a good mine about two miles west of Modock, wbich will yield a large quantity of good ore carrying both gold and silver. The Sorba mine, at Darwin, owned by D. C. Lane, is being exclusively developed and put in condition to be worked on a large scale. It is said that J. J. Morton has an excellent property at Snows Canyon, a rich strike having heen recently made. Tbere is a good deal of activity in mining interests all over soutbern Inyo and 1895 will undoubtedly he a prosperous year.

Placer.

THE MARGUERITE MINE.—*Republican:* Some very fine rock from the Marguerite mine is exhibited by its president, Geo. Schmitt. The owners of tbis mine are much encouraged from the present development. A new pump will immediately be put in to clear tbe mine of water, and soon a chlorination works will be erected to reduce the ore. Tbe right kind of men bave bold of this mine, and if there is anything in it they will find it out.

NOT CONSISTENT.—*Herald:* The anti-debris men of tbe valley are doing everything in their power to prevent the Legislature from making an appropriation to construct dams for the impounding of debris from the hydraulic mines. We bave heard of hogs hut they take the cake. They claim it a private industry and that the proposition has no right to receive financial support from tbe Government. They lose sight if the fact that the dams are for their own protection and not tbe miner's; that it is to keep the debris from ruining (?) their land and filling the river beds. Why not, "live and let live?" Why do the valley people keep agitating this question when they know—if they would admit the truth—that by construction of dams their lands and rivers are safe? Come, neighbors of the valley, give the miner a chance.

Sierra.

AT ALLEGHANY.—*Tidings:* Matters are at a comparative standstill in camp at preseut on account of the storm. Snow is still about ten feet deep at Kanaka creek, where are located several mines and mills. The Gold King mine, the Rising Sun and the El Dorado, have each erected a ten-stamp mill during the past year, the two former running by steam power, the latter by water. The Mariposa, on the same creek, has no mill, but the owners have been working quite a force of men in developing the mine, with bright prospects ahead. The El Dorado has sufficient ore on its dump to keep the mill running for four or five months. Tbe Gold King and Rising Sun are also taking enough good rock from their properties to keep their mills at work. The last storm continued without cessation for eight or nine days, and by recent slides the water ditches became blocked. It is thought that the prospects about Alleghany for the coming season are excellent. The mills now in operation will prove that profitable workings are possible, and this will stimulate development work in other mines, and prospecting on all sides will be resumed.

The Lake Valley mine did a great deal of preparatory work last fall and summer. A sawmill and a roaster were erected. The framework of a 20-stamp mill is up and an electric power plant on the ground, hut not in position.

San Bernardino.

C. O. Barker of Banning and J. C. Fish are the owners of the Somerfield gold mine near Salton on the Colorado desert. This property has been developed by a shaft 300 feet deep, and at that depth a drift is beiug run, all in ore.

Mr. Stewart, who formerly owned the store at Keystone, has bought the five-stamp Shadow Mountain mill, and as soou as a few alterations are made will start up the mill on ores of that district. The mill is eight miles distant from the principal mines.

Both the Bronze and Boomerang mines at Vanderbilt reduced their force of miners during Christmas and New Year weeks, and have put very few of them back to work again. There are several idle men in camp and more coming in daily, most of them needing work very badly.

The Holcomb Valley Gold Company has bad supplies cut short by the storms, the road to Holcomb being completely blocked by large piles of snow. The company expected to get in all their uew machinery tbis winter, to make an early start in the spring, hut it is doubtful now if they will be able to accomplish it. They are sinking several shafts, a large one for water and another (the Nelson) for bedrock. When they reach the deep bedrock you may expect to see the yellow metal at a discount.

Metzger Bros. have been working their two-stamp mill snccessfully, now having plenty of water.

"Lucky" Baldwin and the Budd Dohlo Company have split on terms. Doble has dissolved his company and will haul away what preliminary machinery they had on the grouud. Baldwin is said to he forming a company of his own, to start the old Gold Mountain mines again in the spring.

The Black Hawk gold district is coming to the front again. Two important strikes have been made within the past few weeks.

Joseph Zanini and hrother have a chloriding contract on one of the Black Hawk Company's miues (the Santa Fe). They have struck a large, rich body of gold ore and are now arrastraing some of the richer rock. The strike is of considerable importauce, as it is in a good, solid formation and the highest point on the company's ground. The ore runs from $20 to $100 per ton.

O. C. Leach has made another rich strike on his Opera mine, the eastern extension of the Black Hawk group. He has uncovered a vein of considerable widtb, two feet of which is high-grade gold ore, perfectly free milling and soft. The footwall has a nice clay wall and gives every indication of a permanent body. The ore has not yet been assayed, but from panning, tests would indicate $50 per tou.

The Morongo Gold Company, Morongo mining district, have settled their difficulties and paid up. Judge Campbell has now the management. The company have let a contract to rnn a tunnel some 400 feet to connect witb two shafts now down 170 feet each. This will give good air, and at the same time develop the mine. They expect to start up their ten-stamp mill in the spring.

The Altuma Gold Company of the same dishave also let a contract to strike their ore ledge at the depth of 300 feet by running a tunnel some 200 feet. They then intend to upraise on tbe vein to the 100-foot level. They think this will open up enough ore bodies to justify good reduction works.

The Rose mine people were about to start up their mill on their new strike at 425 feet in depth, when the snow intervened. F. A. Reed has beeu appointed mill superintendent. The snow did not fall so heavily in this part of the county, and they expect to commence operations in a few days.

NEVADA.

The following is condensed from official weekly reports: Consolidated California & Virginia—1650 level—Have continued to stope out ore from the new ore body above and below the sill floor of this level from the sixth floor up to the twelfth floor. On the twelfth floor a south drift started at the south end of the stopes has been advanced 16 feet in a quartz formation which assays $15 per ton. On the ninth floor, which is the first floor above the sill floor of this level, the south drift has been advanced 15 feet; total length, 65 feet; face in porphyry and quartz of low grade. At a point in this south drift 10 feet back from its face have excavated out on tbe east side in ore averaging $40 per ton. 1750 level—Have stoped ore from both sides of the winze sunk from the 1700 level north and south, from the second floor up to the seventh floor. The ore in this range has depreciated in value. On tbe fourth floor a north drift started at tho north end of the stopes has been advanced 15 feet to a point 30 feet north from the winze, running in quartz of low grade. Have extracted during the week 350 tons of ore, the average value of which per mine car samples was $43.89 per ton. Have resumed sbipping ore to the Morgan mill, which resumed running February 6th.

In tbe Opbir mine some quartz carrying a low assay is still heing cut while prospecting above tbe 1465-foot level. In the Central tunnel workings of the mine work in tbe face of the northeast drift No. 3, from the southeast drift, on the 250-foot level, has cut through clay and tapped a flow of about five miuer's inches of water, which bas temporarily stopped work at this point. At a point in this drift, 46 feet in from its mouth, a north drift bas been advanced 17 feet, and its face is in an old stope showing fillings assaying $6 per ton. The work 117 feet above the tunnel level in the northwestern part of the Ophir ground has been confined to the repairing of drifts and other openings. On and above the 1465 level of tbe Mexican mine there have been no changes during the week. As joint work with the Ophir Company, are making repairs in the Ophir shaft at the 1100-foot level and upward.

In the Hale & Norcross mine, on the 975-foot level, the streak of good ore in the face of the south drift from No. 1 west crosscut continues the same as previously reported. Have opened a small station 30 feet below the 975-foot level, in the upraise from tbe 1100-foot level, and have started a west crosscut for the purpose of intersecting this ore streak at the additional depth. This crosscut was out 10 feet at the close of last week, and its face was in porphyry and stringers of quartz. During tbe week have extracted from the 975 level of the Norcross seven cars of ore, which averaged, per car sample, $54.28 per ton. In the Best & Belcher mine, on the 250-foot level, the north drift from the bottom of tbe joint Gould & Curry winze is out 56 feet, passiug through porphyry aud quartz, and the south drift, which the Gould & Curry Company is runuing from the same point, is out 38 feet in the same material.

In tbe Sierra Nevada mine the northwest lateral drift from the Layton tunnel has reached the footwall, and at a point 340 feet from tbe mouth of the tnuuel a southwest drift has been started, with the face in low-grade quartz.

On the 900-foot level of the Union sbaft tbe joint west crosscut from the south lateral drift, 1520 feet west of the shaft, is in 469 feet, with the face in clay, quartz, porphyry and a little water.

In the Chollar during the week extracted 221 tons of ore: average value per battery sample, $20.64. The south drift on the third floor above the 550 level is out 61 feet. It has cut in its course a length of 15 feet of fair-grade ore about two feet wide. Shipped to Carson Mint bullion of the par value of $6654.76, giving coin returns of $3924.16.

In the Bullion mine the west drift, 820 station, Ward shaft, has been extended 15 feet during the week; total length, 1359 feet; face in hard porphyry.

In the Alpba Con. mine, have advanced the north lateral drift on the 450 level 15 feet; total length, 115 feet; face in porphyry and quartz.

In the Justice mine the header in branch drift from the main tunnel was advanced 25 feet. Have broken in the mine and have ready for sbipment about 125 tons of ore. The Washoe mill resumed crushing ore on January 29th.

In the Occidental, from the west ledge above the 400 level they have extracted about six tons of ore of the average assay value of $27 per ton, as per car sample. The west crosscut on the 500 level, at a point 165 feet west of main ledge, has developed a new ledge showing about two feet of ore, which gives average assays of about $30 per ton. Have commenced to drift on the new find both north and south.

In the Alta they have hoisted and delivered to tbe mill 55 cars of ore from the 825 level, the average value of which, according to car samples, is $36.28 per ton. The ore body is extending south and looking well. Started the mill on the 28th ult. Battery samples average $28.86.

ON THE COMSTOCK.—Dan DeQuille writes: There is little change in the mining outlook. Con. Cal. & Virginia is still in the lead and is yielding about the usnal quantity and quality of ore.

The Savage mine is sbowing improvement above the 1050 level, where ore assaying $28.78 is being obtained.

The Crown Point is yielding nearly 600 tons of gold quartz per week. This ore pays very regularly a little over $9 a ton.

The Alta mill has started up on ore, the average assays of which are over $32 a ton. All the ore bins are full to overflowing.

The Justice mine is now yielding over 100 tons a week of ore that pays $10 a ton.

The Hale & Norcross, Chollar, Potosi, Occidental and other mines tbat are producing ore are yielding about as nsual. Exploration work in other mines gives employment to a considerable number of men. Still there are on the lode a great number of idle mines. There is little chance of these finding work here, though many among tbem are old and experienced miners. Occasionally some of these men are sent for to fill good positions in Mexico and other mining countries. Comstockers in other lands who are in a position to employ men do not forget old friends on the mother lode.

The DeLamar, Monkey Wrench or Ferguson district has become celebrated for its rich gold mines during the past two years. It is a young gold field, not being over two or three years old, but it is one of the most promising regions in the State. The town of DeLamar is located among the mines and is a flourishing camp. It is probably 100 miles from Pioche, and is only reached after a long stage journey. There are something like 800 men in the district of DeLamar at present. Tbe April Fool and Jim Crow are two of the leading mines in the district.

ALASKA.

The Lane-Hayward-Campbell Company are talking strongly of putting up a 100-stamp mill on their Silver Bow Basin property. The bandsome little fortune wbich bas partly been taken and partly now lies revealed in Fuller First, demonstrates the great value of this group of claims, and the proprietors do not intend that tbe $500,000 recently paid for them shall very long remain there uncovered.

N. S. Trowbridge, superintendent of the Bald Eagle Mining Company at Sum Dum, in his report to the company, has recommended the construction of a ten-stamp mill on the property, and preparations are now being made for its erection as early in the spring as the weather will permit. The returns on the ore shipped by this company to the smelter at San Francisco last summer were very satisfactory, and it is from this and the superintendent's report that the company has decided to put up a mill.

ARIZONA.

The Antelope mine, situated in Pinal county, and belonging to Tucson parties, is now about in order for making money for its owners. Tbe assays have always been rich enough and the deposits of extent to gratify the possessors. The gold is so fine, however, that it has been saved with difficulty, and a good deal was lost in the slimes. It is said that by the present process of cyanide workings, with steel Cornish rolls, tbat eighty per cent of the gold can be saved. Two cyanide tanks are now in process of construction in Prescott. Iron rolls were tried at the mill, but they did not prove a success. They will therefore he replaced with steel rolls as soon as the latter arrive.

BRITISH COLUMBIA.

A GOLD BONANZA.—Butte *Inter-Mountain:* There is a mine located in the West Kootenai district, British Columbia, which has a wonderful history—the War Eagle. It is owned by P. Clark of Spokane and some Montana men. It was bonded by Mr. Clark in May last year for $23,750, developed by him by a series of tunnels and paid for before the bond expired. Since that time it has developed a wonderful richness, and promises to be a producer for years. It is already a steady shipper, and is now producing fifty tons a day, which are shipped over the Spokane & Northern and Great Northern to Great Falls, where tbe smelter runs show it to average $43 in gold, $5 in copper and $2 in silver. There are seven feet of that sort of ore in the mine. So far the total cost of mining, hauling and reduction is $20 per ton, which leaves a net profit of $30, so that ou the present output of fifty tons per day there is a clear dividend of $1,500 a day for tho stockholders. There is no stock deal on, the gentlemen who own the shares are on Easy street. The history of the transaction, viewed in the light of results, is wonderful. Mr. Clark knew the ground was rich, but he had to wait for over a year till the former holders of the hond on the property threw it up as a losing venture. The pay ore was a little farther up the hill, and at the proper time Clark went straight to the spot and began taking out gold. He struck the Poorman ledge in Canyon creek the same way.

TRAIL CREEK DISTRICT.—The Le Roi is producing and shipping an average of thirty tons of ore a day. The main shaft is down 355 feet and the company is pushing the work on the 300 and 350 foot levels, with a force of fifty men.

The ore from the Le Roi at present comes down over the Spokane Falls & Northern railroad and goes to the United Smelting and Refining Company's works at Helena, netting a satisfactory profit.

COLORADO.

YOSEMITE PLACER MINES.—At the Yosemito, on tbe line of Gilpin and Boulder counties, 27 miles from Denver, last season they ran two streams from a four-inch and a five-inch nozzle, under 125-foot head of water. Tho Denver *Republican* says:

"While California is looking to it that Colorado does not pass it in the quantity of gold produced this year, Colorado miners are beginning to employ the methods of the California placer miner in working the gold-bearing bars. While Colorado teaches the world how to mine and smelt silver and gold when found together in lode ores, California has best learned the value of placer ground and how best to work it. Her miners know that the few cents' worth of gold in a yard of dirt cannot be shoveled into a sluice aud washed with any degree of profit, and appreciate the importance of first making large expenditures for hydraulics, and they have built great plants of this nature in great number. Colorado, on the other hand, has attended to advancing tbe silver industry, and few hydraulic plants worthy of the name have been put in. That tbe change is coming is evident in the work now being done in Clear Creek canyon, in the Tarryall district, Alma, Fairplay, Montgomery, Breckenridge, and especially on South Boulder creek, where of late years much attention is being paid to the old bars tbat in the early sixties were washed by pan, rocker and sluice miners.

"The Yosemite Hydraulic and Mining Company has for three seasons heen operating in South Boulder, on the glacially deposited bars brought down in the ages of which there are no record from the lodes of Perigo mountain and its neighbors in the Gilpin county belt. T. B. Ludlum, a mining engineer of wide experience in the Dutch Flat and Gold Run districts of California, has directed the putting in of a plant that has cost many thousand dollars, though no more than is often spent in equippiug and developing a lode mine, and the resnlt is one of the best adapted plants to placer washing that has ever been constructed in the State.

"To draw the waters of South Boulder creek away from the natural channel, the Yosemite Company has a channel flume 1200

feet long, 9 feet wide on the bottom and 5 feet high; a channel 1100 feet long is being cut through a hill to connect with this. To furnish hydraulic force for washing the bars, a ditch a mile and a half long has been built to bring the water into a penstock with double compartments 12x12 feet and 14 feet high, giving a head of 125 feet and flowing 5000 miner's inches of water. The washing flume is 1120 feet long, on a 2½-inch grade, and is made up of 12-foot sluice boxes, 48 inches wide and 30 inches high, and 8-inch deck boards run the full length. These are lined throughout with block riffles 8 inches high and from 10 to 25 inches in length, after the pattern in use in California. At the lower end of the flume a novel construction to save the flour gold which has escaped the block riffles is made—in effect an undercurrent which carries the dirt under and drops it into a lower box 12x36 inches in size and 14 inches high. In this 180 riffles 1¼x3 inches wide are set on edge and covered by strap iron three-fourths of an inch apart, and the sand passing over that, the smallest globules of the amalgam are precipitated in quiet water and lodged, while the washings that may have carried them that far slip away.

SAN JUAN PLACERS.—*Denver News:* Major J. W. Hanna is from Montezuma county, where he has been testing various machines, each of which was warranted to be the best machine ever invented for separating gold from placer dirt. After spending a great deal of time in the work, Major Hanna has decided to make a thorough test of the electrical process, and has brought with him to Denver a quantity of gravel from the bed of the San Juan river. If the tests are successful a carload of gravel will be brought to the city and a final result reached in regard to the process.

"I never get excited over mining ventures," remarked the Major yesterday, "but after years of practical experience along the San Juan river, I am convinced that the region will become the greatest gold-producing district in the United States. I have 500 acres of placer that assays $3 to the cubic yard, and in many spots much higher. The highest amount I have been able to extract by processes attempted on the spot is sixty cents a yard. I have fully tested eight different machines, but not one of them meets the demand. If the electrical process will do the work, there is no limit to the wealth that can be taken from the placers of the San Juan river."

In the opinion of Major Hanna, the gold is contained in small particles of quartz, and while it is chemically free it is not mechanically free. The successful process requires that the quartz shall be pulverized, and it is upon this plan that the experiments will be made this week in Denver.

The visitor states that 100 to 150 men are washing the sands of the San Juan river this winter and are realizing $3 to $5 a day for their work. Ordinary hand rockers are used. The sand is fifteen to twenty feet deep, and the river for 100 miles below Durango presents an inviting field for men who are willing to labor. Major Hanna says that his faith in the San Juan placers increases steadily as he learns more of the gold values in the sand.

Grant Bros., of Salt Lake, have staked nearly 4000 acres of land on Sand and Bear creeks, near Garrison, for placer. They are there now testing a machine with which they expect to work it. If the test is satisfactory they will put in a $175,000 plant.

IDAHO.

A GOLD STRIKE.—Emmett *Index:* A three-foot ledge of free gold quartz was recently discovered about three miles from Marsh postoffice that promises to be the most valuable strike made in this part of the country in years. The discovery was made by Messrs. Austin and Hall, and assays of samples of the rock show as high as $231 to the ton in gold. The ledge was found on the hill directly above the rich placer mines of A. G. Church, and it is believed the strike solves the question as to where the gold came from that these rich mines have yielded for the last score or more of years. The ledge consists of hard iron rock in which the yellow metal is visible to the naked eye. There will doubtless be considerable activity in mining in and around Marsh the coming season.

MEXICO.

The mining scheme in Sonora in which are interested Messrs. Williams, Howell and Clawson of Bisbee and W. C. Green of Fairbank, is reported to be one of the most promising projects anywhere in the country. Their workings are on the San Miguel river about sixty miles east of Magdalena, and can also be reached from Imuris. The placers are very rich and will be worked on an extensive scale by hydraulicking.

MONTANA.

A GREAT PLACER ENTERPRISE.—*Mining Reporter:* Henry Albertson & Co. are the lucky owners of a valuable placer property at the head of Bilk gulch, on the line between Deer Lodge and Granite counties. They are erecting a pumping plant, the like of which has not been heretofore attempted by any other company in Montana. The pipe throws 950 inches of water per minute, through a nine-inch pump 800 feet in height, covering a vertical distance of 3600 feet to an immense box reservoir. This water is to be used for hydraulics on ground that averages from ten to fifteen cents to the pan, and can be worked six months out of a year. There are no heavy boulders in the bar, and the property is considered very rich when once controlled by a sufficient head of water.

NEW MEXICO.

Record: Since last summer a Kansas City syndicate has had a force of men making tests on 500 acres of placer ground on the Galesteo creek in south Santa Fe county. Three thousand dollars were invested in a prospecting plant consisting of an engine and a boiler, steam hoisting apparatus, pump, derricks and an air caisson twenty-nine feet long, in two sections, similar to that used in laying the foundation of bridges. Two tests have shown from 5 cents to $2.50 in gold per cubic yard. That three feet above bedrock ran $3.78 in gold, and F. E. Nettleton, mining engineer in charge, states that a plant to operate on a large scale will be put in at once.

This plant will be capable of handling 10000 cubic yards of earth and gravel per day, and will have sufficient power to lift up six inches of the bedrock. The estimated cost of handling the material is 15 cents per cubic yard.

Cerillos *Rustler:* The sale of the Good Hope, at Allerton, has been made to a Denver company that will develop it. The consideration is reported at $23,000.

A Golden correspondent writes: We have gold, silver and copper ores, the copper ores also carrying considerable gold, which makes such very desirable. While we have high and low grade free-milling ores, we have also a great deal of refractory gold ore, which can not be treated on a stamp mill.

OREGON.

Ashland *Tidings:* The miners were all down from the Ashland mine Saturday, and $1500 which had just been cleaned up from the plates at the mill in town was divided among them, giving them about $40 each, and putting them in considerably better humor. This cleanup was the result of only a short run. Some splendid rock has been sent down from the mine lately, and the men say there is plenty of it in sight to bring the owners of the mine out all right.

SISKIYOU

QUARTZ AND PLACER

Gold Mines.

Parties desiring to invest in paying quartz or placer gold mines or in undeveloped mines of demonstrated merit, in Siskiyou county, will learn of several excellent chances for safe and profitable investment by addressing

Electrical Progress.

Electrical Rapping and Talking Table.

In a receut uumber of *Der Stein der Weisen*. Vienua, is described an ingenious piece of electrical apparatus that is withiu the power of any clever workman to construct. The following translation of the description is from the *Literary Digest:*

The varied applications of electricity in the present day surely put to the blush the deeds of wonder of the old magicians, as well as those of the modern prestidigitator. In the following paragraphs a piece of electric apparatus for an entertainment in parlor-magic will be described, namely, a rapping and talking table. It is an ordinary small table or stand with a rather strong top, having in the middle a circular hollow surrounded by a ring-shaped one. The whole is covered with a plate of wood about one-eighth of an inch thick. The foot of the table is hollow, and has at its lower end a little chamber in which is hidden a Leclanche element, aud which is accessible by means of a lid. From the battery two wires lead to two springs; these agaiu press against two half rings of metal, which are so fastened inside the top of the chamber that when the element is iu action there will be au electrical contact with them. They are in connection with two wires that lead from the foot of the table upward. One of these wires is connected to a notched metal ring that lies in the ring-shaped hollow on the table-top; the other connects with one eud of an electro-magnet coil in the middle of the table-top. The other end of this coil is in electrical contact with a flat metal ring that is fastened to the thin wooden cover of the table-top directly over the notched ring, without touching it. If the open hand be now placed on the thin wooden layer directly over the two rings, the electric current will be closed and the electro-magnet will attract its armature, which is fastened to the thin layer. This makes a loud rap, and when the current is broken there is au other rap. Of course the movement of the hand must uot be perceptible.

Each of the wires that lead upward through the leg of the table is also connected with a longer wire that leads through the lower end of the leg. Both of these are so arrauged that they may be led underueath a carpet or rag and connected to a telephonic transmitter in another room. If the transmitter be uow spoken to, the table will serve as a telephone receiver and reproduce the words, of course, much to the mystification of the uniuitiated.

Replace Lamps Often.

Users of the incandescent electric light should avoid the idea entertained by many people that the value of lamps depends entirely upon the number of hours they will burn. Some lamps last a long time beyoud their allotted life, and it is economy to promptly break all incandescent lamps after they have burued for a certaiu number of hours. A "three-watt-per-candle" lamp of recent constructiou may be started at a voltage sufficient to derive 16 c. p.; and, after burning from 50 to 100 hours, the c. p. will increase with the same pressure, or voltage, to seventeeu candles or over. From this poiut—say ninety hours—the c. p. of a lamp decreases gradually until, after burniug 500 hours, it has probably fallen to about eleven candles. This decrease in c. p. is not due to blackening of the bulb, which sometimes takes place, but to entirely different causes. If the voltage be increased to obtain an illumination of twenty to twenty-five candles from a 16 c. p. lamp, the probability is that the lamp started at 20, will rise to 21 c. p. iu about fifty hours, then gradually falls to eleven candles iu 450 hours, and will probably give out altogether in about that length of time. The lamp started at twenty-four candles, will rise to twenty-five in about tweuty-five hours, then fall to seventeen candles in 100 hours and to thirteen candles and fail in 200 hours. A voltage not above the capacity of a lamp is then the most economical, and it is better to break a lamp at 300 hours when it gives 13 c. p. than to run it 200 hours longer and have the light fall from thirteen to eleven candles. The expenditure for power thus wasted would much more than pay the increased cost of a liberal use of lamps.

The ordnance department of the United States Navy has, it is said, practically determined to operate the guns and turrets of some of its ships by means of electricity for the futnre. It is not yet intended to actually displace steam by the new motive power, but to so place it that in case of accident it may be switched on, and thus prevent the gun being thrown out of action. It is a wise step to make electricity at first only accessory to steam; but that, on the whole, electric motors are a preferable means of working guns has been determined after a series of experimeuts, the stringency of which was intended to bring out weak points if such existed. The advantages of the system are considered to lie in the greater simplicity of electric conductors compared with steam pipes, both as regards the ease of carrying them round bulkheads and the smaller surface exposed to injury, together with the facility with which they cau be repaired. Chief of all advantages is cousidered the greater simplicity of manipulatiug the controlling switch as against steam valves. A single lever, according to the system devised by Captain Samson, effects the operations of training and elevating.

Sunlight cau be produced on the earth at will, according to Nicola Tesla, the eminent electrician. He says that the light of the sun is the result of electrical vibrations in the 94,000,000 miles of ether which separate us from that great lumiuary, and does not proceed from a great central fire, as the scientists have all along held. If these vibrations can be produced the light will follow. The rapidity of the vibrations in a second necessary to produce desired result is, he says, expressed by the figure five with fourteen ciphers annexed; and he is now trying to build a machine which will produce these vibrations. The attempt will be of considerable scientific interest, whether carried to a successful issne or not.

The Chicago *Times* says: "More than one-half of the jangling of telephoue bells will be silenced iu Chicago during the next six months. Within that time the Chicago Telephone Company will have placed in operation its uew system of signals. A person using a telephone will be able to reach the one with whom he desires to talk, say what he wauts to and end the conversation, all without the jangling of a bell. The sigual to the operator in the exchange will be given by flash lights from an electric lamp."

A paper recently read by J. A. Baylis before the Can. Elec. Association deals eutirely with the electrolytic corrosiou of underground pipes and electrical conductors by stray earth currents. The remedies which Mr. Baylis suggests are: Grounding positive pole of dynamo and putting the negative to the liue; breaking metallic continuity of the pipes and cables; frequent reversals of polarity of the street railway current. But eveu these are uot thought to prove wholly corrective of the trouble.

Electricity has now beaten the record of the goldbeater, and can produce a foil of the metal from five to ten times thiuner than ordinary gold leaf. Joseph Wilson Swau, the well-kuown chemist of electric-lightiug fame, has presented to the Royal Society specimens of this wonderfully thin foil made by depositing gold on copper with the electric current and then dissolving away the eopper from it with perchloride of iron.

GATES ROCK AND ORE BREAKER

OVER 3000 IN USE THROUGHOUT THE WORLD

PRODUCES A MORE PERFECT CUBIFORM MATERIAL AND A GREATER QUANTITY IN A GIVEN TIME PER HORSE POWER USED THAN ANY OTHER CRUSHER ON EARTH.

CAPACITIES UP TO 150 TONS PER HOUR. NINE DIFFERENT SIZES.

WE HAVE BUILT THE LARGEST STONE CRUSHING PLANTS IN EXISTENCE

GENERAL MINING MACHINERY

OF EVERY DESCRIPTION.

TREMAIN STEAM STAMPS

Connorsville Blowers, King-Darragh Concentrators, Stamps, Hoists, Rolls, Pans, Settlers, Smelters, Metallurgical Appliances, Etc.

And Chemical Laboratory

524 Sacramento Street, San Francisco, Cal.

New Land Office Rulings.

The Secretary of the Interior has recently rendered the following new decisions:

First—Land embraced within the claim of a qualified settler at the date a railroad grant becomes effective and is excepted by such claim from the operation of the grant.

Second—Evidence of voting will raise a presumption of citizenship, as fraud on the part of the voter is not to be presumed.

Third—The sale of a soldier's additional homestead right and attempted transfer thereof by power of attorney, to locate the right of said certificate, is made good in the hands of the purchaser by the act of August 18, 1894, and such purchaser is accordingly entitled to the possession of the certificate.

Fourth—Timber and land entries made for speculative purposes are fraudulent and will be canceled.

Fifth—In the investigation of a case where fraud is alleged against an entryman, proof of other acts of similar nature done contemporaneously, or about the same time, is permissible to show such extent.

Sixth—Repayment of fees and commission may be allowed where the entryman, to avoid conflict resulting from an error in the local office, in good faith, relinquishes his entry and takes another tract.

Seventh—A deserted wife may make a homestead entry, with credit for previous residence on the land, where her husband's entry thereof is canceled for failure to make final proof within the statutory period.

Eighth—A joint entry cannot be allowed where there is but one residence and set of improvements maintained and occupied in common by the parties, with the intention to take separate tracts when the land is open to entry.

Ninth—The possession and occupancy of a tract by a qualified settler at a definite location of a railroad grant, serve to except the land covered thereby from the operation of the grant, even though the settler at such time supposed the land belonged to the railroad company.

Tenth—The expiration of a pre-emption filing without final proof and payment, will not alone be accepted as proof of abandonment of the settlement claim at such time so as to relieve a railroad grant therefrom.

Irrigation Run Wild.

The *Irrigation Age* contains some entertaining correspondence. It appears that a Mr. Young wrote an article for the above paper under the title of "The Mighty Colorado and Its Irrigation Possibilities," which article contained some statements remarkable enough to stir up R. B. Stanton, who happens to know something about the Colorado, as well as the country in question, and Mr. Stanton replies to Mr. Young at some length. Mr. Young says that there are millions of acres awaiting irrigation and suggests that where this land is shut in by high ground, tunnels and siphons could be used, which is a simple suggestion to make. He proposes that a dam should be built somewhere along the course of the Colorado and its waters diverted into Death valley, filling that valley and reclaiming the surrounding desert. A map given by Mr. Young locates definitely the position for the dam, and the course of the canal and the country to be irrigated. An examination of the contour maps of the United States Geological Survey discloses some interesting facts. It shows that the proposed canal would be 150 miles long, and that, as high land with several mountain ranges lies between the Colorado river and Death valley, the canal may be made with only one through cut. This, however, would be 150 miles long and have a maximum depth of 2500 feet. Mr. Young suggests, however, that a tunnel might be used which would be only 125 miles long. To get the water from Death valley to the various tracts to be irrigated would require only two more open cuts, one of 50 miles and another of 150. Mr. Stanton suggests that it would be folly to stop there, but the canal should go straight on through the Sierra Nevadas and turn the surplus water into the San Joaquin valley, which would take only one more tunnel about 125 miles long.

Every Inventor Wants a Good Patent

Or none at all. To secure the best patents Inventors have only to address DEWEY & Co., Pioneer Patent Agents, No. 220 Market St., San Francisco.

There are many good reasons why Pacific Coast Inventors should patronize this Home Agency.

It is the ablest, largest, best, most convenient, economical and speedy for all Pacific Coast patrons.

It is the oldest on this side of the American continent, most experienced, and in every way reliable.

Conducted from 1863 by its present owners (A. T. Dewey, W. B. Ewer and Geo. H. Strong), this agency has the best knowledge of patents already issued and of the state of the arts in all lines of inventions most common on this coast.

Patents secured in the United States, Canada, Mexico, all British colonies and provinces, England and other civilized countries throughout the globe.

Caveats filed, assignments duly prepared, examinations made, and a general Patent Agency business conducted.

Established and successfully and popularly conducted for nearly thirty years, our patrons number many thousands, to whom we refer with confidence, as men of influence and reliability. Old and new inventors are cordially offered the complimentary use of our library and free advice, etc. No other agency can afford Pacific States inventors half the advantages possessed by this old, well-tried and experienced firm.

UNITARIAN LITERATURE sent free by the Channing Auxiliary of the First Unitarian Church, cor. Geary and Franklin Sts., San Francisco. Address as above. Mention this paper. *

Market Reports.

The Markets.

SAN FRANCISCO, Feb. 7, 1895.

The prophesy that "silver will advance before long" is still deferred in fulfillment, though the trend of events and the working of natural laws insure its realization. Free coinage of silver—the new British trade dollar—is reported from Bomhay, and it is predicted that the East Indian mintage will supplant the rupee. Meanwhile, another bond issue is announced from Washington, the pouring of water through a sieve being still considered statesmanship there.

There was a slight decrease in metal prices during the week, as shown below.

New York Metal Market.

NEW YORK, Feh. 7.—PIG IRON—Scotch, 19@20c; American, 9.50@12.50c.
COPPER—Brokers', 9⅝c; exchange, 9.80c.
LEAD—Brokers', $3.02½; exchange, $3.12½.
TIN—Straits, 13¾c; plates, ——c.
SPELTER—Domestic, $3.20.

New York Prices.

NEW YORK, Feh. 7.—Following are the closing prices for the week:

	Silver in—			
	London.	N. Y.	Copper.	Lead.

Mining Share Market.

SAN FRANCISCO, Feh. 7, 1895.

A drop in the early part of the week, caused in part hy the unfavorable weekly report, temporarily satisfied the bears, the market heirg at the mercy of any determined influence either way. At the delinquent assessment sale of the Ophir hut 120 shares were offered for sale.

The Standard Con. M. Co. holds its annual meeting on the 18th. The Bulwer Con. assessment is delinquent next Friday. The Con. Cal. & Va. declares a $54,000 dividend to-day. The De Lamar Mining Company of Idaho, owned and operated hy English capital, has paid a dividend of 1s per share in London. The amount is $100,000, and is at the rate of 20 per cent per aunum.

During the month of January the sales of mining stocks at the San Francisco Board amounted to 641,000 shares.

Mining assessments falling delinquent this month amount to $73,608, of which Nevada mines want $60,108, California $8500, and Mexican mines $5000.

The following shows the cash balances of some of the mining companies on the 4th inst.:

Alpha	$7,275	Hale & Norcross	$24,401
Alta	5,982	Justice	668
Andes	6,703	Kentuck	4,404
Belcher	3,007	Lady Wash'n	2,335
Best & Belcher	18,134	Mouo	4,935
Bullion	2,713	Mexican	19,423
Bulwer	3,090	Navajo	3
Bodie	14,640	Nevada Queen	233
Caledouia	3,477	Occideutal	155
Challenge	670	Ophir	13,910
Chollar	6,853	Overman	8,548
Church	8,697	Potosi	22,522
Con. Imperial	1,139	Savage	10,118
Confidence	776	Scorpion	1,132
Con. New York	1,002	Seg. Belcher	409
Cou. Cal	137,323	Silver Hill	1,915
E. Sierra Nevada	236	Silver King	1,047
Exchequer	2,618	Sierra Nevada	1,975
Gould & Curry	1,315	Standard Con	48,713
Grand Prize	971	Union Con	16,932
Gray Eagle	1,377	Utab	2,605

During January there were disbursed to employes in Virginia City sums as follows: Hale & Norcross, $2616.50; Andes, $900; Con. Cal. Va., $10,595; Mexican, $2133.75; Ophir, $3677.75; Best & Belcher, $2379; Gould & Curry, $1432; G. & C. and B. & B. shaft, $124; Alta, $2223.75; Savage, $2754; Justice, $1300; Crown Point, $7798.66; Yellow Jacket, $2733; Confidence, $90; Challenge, $90; Belcher, $3198; Seg. Belcher, $590; Chollar, $5059; Potosi, $2476; Union Shaft, $2841; Ward Shaft and Bullion, $714; Sierra Nevada, $811; Alpha and Exchequer, $726; Occidental, $900; Silver Hill, $245; West Con. (estimated), $1800; Nevada Mill (estimated), $2500; Electric Light (estimated), $500; Water Company (estimated) $3000; Quartz Mills (estimated), $10,000; total, $77,158.41.

The following illustrates the changes of the week:

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING JANUARY 29, 1895.

533,344.—VEHICLE SPRING—A. W. Burdick, Fresno, Cal.

533,056.—SCAFFOLD—Cruson & Robkins, Lebanon, Ogn.

533,168.—LAMP STOVE—Furrey & Hollman, Los Angeles, Cal.

533,124.—SAWMILL OFFSET—D. B. Hanson, S. F.

533,195.—DENTISTS' TOOL—A. P. Hays, Los Angeles, Cal.

533,367.—SPRAY NOZZLE—J. McBoyle, Oakland, Cal.

533,142.—TELEPHONE—Sabin & Hampton, S. F.

533,400.—AIR INJECTOR—J. W. Stanley, Oakland, Cal.

533,380.—SEWING MACHINE—G. W. Stewart, Chehalis, Wash.

533,102.—GAME—Mary Thomson, Los Angeles, Cal.

23,962.—DESIGN—PIN HOLDER—E. H. Ellis, Pasadena, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

A Word of Caution.

Tbe necessity of keeping close watch over mining claims and of taking all legal steps to perfect title has been shown in the Coulterville district lately. In one instance a mine (patented, we believe), upon whicb a mill was in operation, was jumped, and several instances are reported where claims have been "appropriated." There are men who will resort to almost any means to secure desirable claims; and even though tbeir efforts do not win, tbe owners are put to considerable expense. A claim is never safe until it is patented; and if a claim is worth holding, it is worth patenting. It is a matter of neglect with most men tbat tbey have not secured patents, but it is liable to prove a dangerous oversight. Now that so many new men are in the country, the likelihood of trouble from this source is increased. It will prove the part of wisdom for every man who has a good mine to secure a patent as soon as possible.—Mariposa Gazette.

South Africa's Gold Output.

The December output of tbe Rand was 182,104 ounces, the highest on record, beating that of September (the previous best) by 5,397 ounces, and tbat of December, 1893, by 35,747 ounces. The year's production is 2,024,159 ounces, an increase of 545,686 ounces over 1893. Tbe magnitude of the December output is partially explained by the inclusion of "sweepings," due to the aunual cleaning up of chlorination plants, and so-forth, wbich made an addition of close on 2500 ounces to the production of the Robinson alonc. Tbe output of January will probably show a reduction in consequence of the absence of these "sweepings," and, besides, the Geldenbuis estate, yielding over 6000 ounces a month, has suspended crushing in order to add to its battery power. On the other hand, one or two other miues are now crushing with an increased number of stamps.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

AIR INJECTOR AND OIL BURNER.—James W. Stanley, Oakland, Cal. No. 533,400. Dated Jan. 29, 1895. This invention relates to a device for hurning oil and combining with it jets of air and steam. It consists of a series of independent separahle air-supply nozzles, a jet tuhe through which steam is delivered centrally through said nozzles and an oil-supply device, with a means for heating the same before it is delivered into the injector. The nozzles have their hases enlarged at right angles to the line of their projection, each of said chambers having a rearward extension hy which it is fitted into the next adjacent one. A cap or casing is fitted to the rear of the nozzle, having a central steam pipe and discharge nozzle aud an annular oil chamher is fitted within the cap around the steam pipe, having a passage through which oil is admitted to one side and a discharge pipe on the other through which oil is delivered into the line of the steam-discharge jet. The oil is heated by the steam and is discharged with the steam, while the air admitted through the series of nozzles assists in the perfect comhustion of the whole.

SPRAY ATTACHMENT FOR NOZZLES.—Joseph McBoyle, Oaklaud, Cal. No. 533,367. Dated Jan. 29, 1895. This device is an attachment for water-discharge nozzles and is used to produce a spray especially adapted for irrigating purposes. It consists of a perforated plate adapted to slip over the end of the nozzle, having the lower part hent at right angles with the perforated portion, a spring clasp projecting upwardly from this part in line with the perforation, so as to clasp the end of the nozzle, a plate adjustahly attached to the outer end so as to be turned more or less to intercept the stream of water discharged from the nozzle. This plate has a rounded end and the surface of it is grooved or corrugated so that when the water strikes it it will he dispersed in a fine spray. The plate may he raised or depressed to change its angle and the device is provided with a means for holding the plate in any desired position.

Assessment Notices.

GOULD & CURRY SILVER MINING COMPANY—Location of principal place of business, San Francisco, Cal.; location of works, Virginia, Storey county, Nev.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 17th day of January, 1895, an assessment (No. 75) of fifteen cents (15c) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, room 69, Nevada block, 309 Montgomery street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 19th day of February, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on TUESDAY, the 12th day of March, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

ALFRED K. BURROW, Secretary.

Office—Room 69, Nevada block, 309 Montgomery street, San Francieco, Cal.

REED MILL AND MINING COMPANY—Location of principal place of business, San Francieco, California. Location of worke, Ferguson Mining District, Helene, Lincoln County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 31st day of December, 1894, an assessment (No. 1) of two (2) cents per share, was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, room 33, tenth floor, Mills Building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 28th day of February, 1895, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on WEDNESHAY, the 3d day of April, 1895, to pay the delinquent assessment, together with the cost of advertising and expenses of sale.

By order of the Board of Directors.

JOHN H. ISHAM, Secretary.

Office, Room 33, tenth floor. Mille Building, San Francieco, California.

BULLION MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Virginia district, Storey county, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 21st day of January, 1895, an assessment, (No. 44) of 10 cents per share was sold on THURSHAY, the 21st day of March, 1895, levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the company, Room 21, No. 331 Pine Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 26th day of February, 1895, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

R. K. GRAYSON, Secretary.

Office, Room 21, No. 331 Pine street, San Francisco, California.

INYO MARBLE COMPANY OF CALIFORNIA.—Location of principal places of business, San Francisco, California; location of works, Inyo, Inyo County, California.

Notice is hereby given, that at a meeting of the Board of Directors held on the 21st day of January, 1895, an assessment (No. 26) of ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, Room No. 15, third floor, Mills Building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 6th day of March, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on FRIDAY, the 5th day of April, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

W. W. SARGEANT, Secretary.

Office—Room 13, third floor, Mills Building, San Francisco, California.

BUMBARTON LAND AND IMPROVEMENT COMPANY.—Location of principal place of business, San Francisco, California. Location of works, in the counties of Alameda and Santa Clara, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 22d day of January, 1895, an assessment (No. 7) of 12½ cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, No. 214 Pine street, room 55, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 28th day of February, 1895, will be delinquent, and advertised for sale at puolic auction, and unless payment is made before, will be sold on THURSDAY, the 21st day of March, 1895, to pay the delinquent assessment, together with coste of advertising and expenses of sale. By order of the Board of Directors.

JABEZ HOWES, Secretary.

Office, Room 55, 214 Pine Street, San Francisco, California.

THE CALIFORNIA DEBRIS COMMISSION, having received applications to mine by the hydraulic process from W. Thomas et al., in the Central Hill Mine, Douglas Flat, Calaveras Co., Cal., to impound tailings behind stone dams in ravines; from Giovanni Rossi, in the Kate Gray Mine, near Volcano, Amador Co., Cal., to impound tailings behind log and brush dams below mine; from J. E. Newsom, in the Shealor Mine, near Volcano, Amador Co., Cal., to impound tailings behind log, rock and brush dam in Sutter Creek; from Giani Remartini et al., in the Rail Road Hill Gravel Mine, near Fourth Crossing, Calaveras Co., Cal., to impound tailings behind a dam on flat ground; and from John Slater, in his mine near Brownsville, Yuba Co., Cal., to impound tailings behind York Mining Co.'s dam, gives notice that a meeting will be held at Room No. 92, Flood Building, San Francisco, Cal., on Feb. 25th, 1895, at 1:30 P. M.

THE

Ore Deposits of the United States.

By J. F. KEMP, A. B., E. M., Professor of Geology, School of Mines, Columbia College.

Second Edition, Revised and Enlarged, New Illustrations.

A practical review of the ore deposits of this country. A valuable addition to up-to-date mining literature, of value to the Pacific coast. Sent postpaid upon receipt of price, $4.00. Address

Mining and Scientific Press,
220 Market Street, San Francisco. Cal.

Coast Industrial Notes.

During '94 1,163,432 tons of coal were mined in the State of Washington.

The Bay City Iron Works Co. has incorporated with a capital stock of $10,000.

The Risdon Iron Works are placing a 100-horse power boiler on the Osborn Hill mine at Grass Valley.

Tacoma, Wash., figures having saved $50,000 in '94 by municipal ownership of light and water furnished.

The subscriptions to the San Francisco and San Joaquin railroad scheme now aggregates nearly $2,000,000 in this city.

W. G. Dodd, of the Union Iron Works, has designed and will shortly put on the market the Dodd ore crusher and the Union concentrator.

The California Telephone and Construction Co. has filed articles of incorporation at San Jose, with a paid-up capital stock of $500,000.

A syndicate of capitalists is reported to have offered the Government $33,000,000 for its entire claim against the Union Pacific Railroad.

Eight Heady-Norbom concentrators were last week sent to the Grand Victory mine in El Dorado Co., and two to the Bald Eagle, Alaska, mine.

The sale of $42,000 bonds for a water system for Ballard, Wash., has been completed by the city council accepting the offer of a Boston house.

There are now in California 675,000 tons of wheat. The loss to the State by the depreciation in the price of wheat for the last three years aggregates $22,500,000.

The Redlands Electric L. & P. Co. will issue $100,000 in bonds, using one-half the proceeds in taking up the original issue and the other one-half in improving the plant.

The Mendocino Lumber Co. have cut the wages of their employes twenty per cent. This, they claim, puts the wages they pay equal to the rate paid during '94 by other companies.

The new "Gold King" amalgamator, manufactured by the Midas Gold-Saving Machinery Company of this city, is attracting much attention from practical mining men. Their headquarters are at 114 First street.

The largest drydock in the world is now under construction at Port Orchard, Wash. A large tract of land on Puget Sound, sixteen miles from Seattle, has been bought for the purpose, and the work of building is well under way.

The coast line of the S. P. R. R. has reached a point on the coast. The track has reached Pismo beach at the townsite of Grover the first place south of San Francisco where the road actually comes down to the ocean front. The work will be pushed forward without delay under the present contract, and through connection between San Francisco and Los Angeles will be made during the coming year.

Electric Elevators.

The Sprague Electric Elevator Company has just closed a contract with the Parrott Estate for the installation of fifteen electric elevators in the Parrott Building now being erected on Market street. Eleven of these elevators are high speed, and four are slow speed sidewalk elevators.

This contract is notable as being for the most extensive elevator plant in Ameriea, if not in the world. The selection of this type of elevator was based upon the highly successful results of six that were placed in the new Postal Telegraph Building, in New York City.

San Francisco has been slow in accepting the electric elevator, but confidence in it having been established, it bids fair to replaee the more expensive elevators now in general use.

PROSPECTING

Mechanics; Mechanical Drawing; Electricity; Architecture; Architectural Drawing and Designing; Masonry; Carpentry and Joinery; Ornamental and Structural Iron Work; Steam Engineering (Stationary, Locomotive or Marine); Railroad Engineering; Bridge Engineering; Municipal Engineering; Plumbing and Heating; Coal and Metal Mining, and the English Branches. Blowpiping outfit and mineral specimens *free* to students. Send for Free Circulars, stating the subject you wish to study, to

THE INTERNATIONAL CORRESPONDENCE SCHOOLS, Scranton, Pa.

The Ideal Steam Oil Refiner

FOR STEAM POWER PLANTS.

The Purity Oil Filter

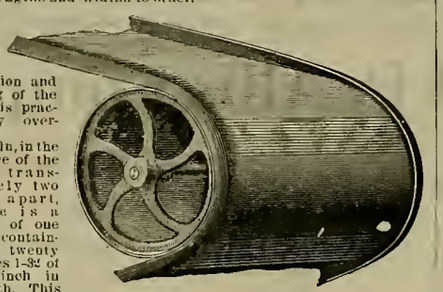
FOR WATER POWER PLANTS.

Will reclaim your waste oil and make it equal and often better than new oil. Will reduce your oil bills 50 per cent and save your bearings. In use with the largest and best plants everywhere. For prices and particulars, address

D. M. DOUB, 137 First Street, San Francisco, Cal.

Blasdel Improved Concentrating Belt.

We keep in stock belts suitable for the Frue, Triumph, Johnston and Tuffock machines, and make all lengths and widths to order.



Practical mill men must see at a glance the advantage of our belts over any other. First, the flanges stand at an acute angle toward the center, therefore readily conform to the change of direction while passing over the end rollers. Thus the vexation and loss occasioned by the frequent breaking of the flanges, as is the case with the old style, is practically overcome.

Again, in the surface of the belt transversely two feet apart, there is a space of one inch, containing twenty riffles 1-32 of an inch in depth. This tends to equalize the pulp and prevents it from banking on the edges, or forming channels. This riffle saves the sulphurets and quicksilver that would escape with the tailings from a belt with an entirely smooth surface.

AGENTS LADIES OR GENTS $75 A WEEK, At home, using or selling Gray Plater, or collecting goods for us to plate. We do all kinds of plating at our works, manufacture the materials and outfits, and teach the art. We sell the only complete outfits, including lathe, wheels, tools and materials for polishing, preparing, plating and finishing everything. Circulars and prices free. Gray & Co., Plating Works, Dep't 4, Columbus, Ohio.

DEWEY & CO., 220 Market St., SAN FRANCISCO, PATENT SOLICITORS.

ESTABLISHED 1863

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S.F.

RUPTURE!

IT has been considered by the medical profession that hernia—commonly called rupture—was incurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But DR. J. C. ANTHONY, of 86 and 87 CHRONICLE BUILDING, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patient no pain, and those living near enough do not lose any time only while in his office once or twice weekly. He guarantees every case he treats, and does not ask a man for a dollar unless he cures him, so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medical College, of New York City.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—GOLD AND SILVER ORES.

SECOND EDITION—PRICE $1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist or the practical miner can mistake his meaning.

The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular," is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:—Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scorification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 130 12-mo pages, with illustrations, well bound in cloth; 1889. Price $1.00 postpaid. Sold by the Mining and Scientific Press, 220 Market St., San Francisco.

Parts II and III.—Gold and Silver Bullion, Lead, Copper, Tin, Etc.

SECOND EDITION—PRICE $1.75.

This book is entitled "Assaying—Parts II and III," and is separate from part I, and treats of Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Zinc, Nickle, Cobalt, etc.

Table of Contents:—Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Volhart's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickle and Cobalt; Chromium; Bismuth; Arsenic; Anthmony; Sulphur; Salt; Note.

One of the methods given for the Assay of Copper is new, original and exact, as is also one of the processes for Zinc.

The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter.

Price, postpaid, $1.75. Sold by the Mining and Scientific Press, 220 Market St., San Francisco.

Books on Working Ores.

BY GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals Without Quicksilver. By GUIDO KUSTEL, M. E.

This rare book on the treatment of gold and silver ore without quicksilver is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is insurpassed in his specialty. Price, $5, postpaid. For sale by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

BY C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant; 164 pages, octavo. Illustrated by twelve lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, $3. Sold by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

BACK FILES of the MINING AND SCIENTIFIC PRESS (unbound) can be had for $3 per volume of six months. Per year (two volumes), $5. Inserted in Dewey's patent binder, 50 cents additional per volume.

Dredging at Dayton

By the Carson River Placer Mining and Dredging Company—Recent Developments.

After some eight years of experimeut. aud at a cost of more than one hundred and twenty thousand dollars, the "Carsou River Placer Mining and Dredging Company" has at last demonstrated that river dredging for gold and silver beariug sulphurets, free metals—including gold. silver and quicksilver—metal bearing sliues from the mills, etc.. is no longer an experimeut, but. from a financial point of view, a decided success. The profits of labor to save these values by means of dredging, screening and concentration depend upon several factors, principally the following:

1. The number of tons of sand, or "pulp," that each concentrator will treat per day.

2. The number of concentrators used; the per cent of concentrates obtained from the pulp; the assay value of these concentrates, and the per cent of this value recoverable by milling or other processes of reduction.

3. The amount of free metal obtainable by amalgamation or other process, and the expense of the whole process of treatment.

The project of the Carson River Placer Mining and Dredging Company originally had for its object an effort to recover simply the quicksilver carried iuto the Carson river from the many mills that worked the ores of the famous Comstock lode. The following, taken from Vol. 4. page 117, U. S. Geological Survey, explains clearly the origin of the company:

"Milling.—In the early days of mining on the Comstock lode, considerable quantities of very rich aud complex ores occurred, and these were treated by washing aud barrel amalgamation. Later, the ores became more facile, and the system of pan amalgamatiou was developed and applied with success. For many years it has been found practical to beneficiate all ores met with by this process, with the aid of bluestone (cuprus sulphate) and salt.

"The success of the process is unquestionably due in a large measure to the chemical action of the iron. Formerly the mills guaranteed a return of sixty-five per cent of the assay value of the ores, but of late years seventy-two per cent is guaranteed, and above eighty per cent is often returned.

"On the whole, however, it is improbable that more than seventy-five per cent of the bullion contained in the ore has been recovered from it, and it is therefore fair to estimate that the ore received has contained at least $400,000,000, of which about three-quarters has reached the market.

"Competition aggravated the evils of scarcity, for as a fixed sum per ton was paid for milliug, it was to the interests of the custom mills to reduce as many tons per day, however imperfectly, in order to compete with one another at a profit. Guarantees of any arbitrary percentage of returns, based on the assay value of the ore, were rarely given, and unless the customer became disgusted with the scanty yield of bullion and withdrew his patronage, the mill owner cared little for the constant waste of metal in the slimes or tailings which were washed away directly or indirectly into the river. Thus the Carson flowed like Pactolus over precious sand, and its bed is lined with ores of varying thickness.

"It is not too much to say that one-third of the ore product, during the early years of mining on the lode, was lost in the production through carelessness, iguorance aud reckless competition."

Iu the spriug of 1893 the company, tired of years of expensive mismanagement and failures and of promises expeusively broken, sent to Dayton the general manager, Dr. O. H. Warren, of Syracuse, N. Y., a gentleman well versed in mechanics, prudent and thoroughly competent to master the task before him. i. e., to determine. beyond the question of a douht, if the values were in the river in sufficient quantities to pay, and, if so, could they be successfully recovered.

Dr. Warren's experiments showed that amalgamation was practically impossible, because of the amount of quicksilver contained in the river material, keeping the plates too moist, and that, for other reasons, blanket sluices were impracticable; so, one by one. all devices commouly used were discarded. until nothiug in use in ordinary milling and mining methods was found practical in this peculiar proposition except the single one of concentration. Then followed a long and exhaustive series of experiments and practical tests with the Woodbury and other standard coucentrators. Upon the results of these carefully couducted tests the estimate of the output of a plant of given capacity was computed, and it was shown, beyond a douht, that a plant of sufficient capacity would pay enormous profits. The Westeru department of the company was then entirely changed and reorganized, by the appointment

STRONG and numerously signed protests are being presented in the Legislature against the proposed tampering with the State Mining Bureau.

NOTHING is ever settled till it is settled right, and so long as the price of silver is set in London, so long will be delayed the proper adjustment of the silver question. There is a proposed combination of American interests to handle the silver product of the country in New York, which is a step in the right direction. It is anomalous and absurd if allowed to continue, that the country producing no silver should control the world's price of that metal. Of course, we are not unmindful of the causes, nor the facts; it is understood that the big purchasers of silver buy in London, and because of that it is in London the price is made. The system must be overturned, and the sales made and the price maintained in the country and by the country that produces the largest percentage of the white metal.

WASHINGTON PAPERS are trying hard to have a State Mining Bureau for that commonwealth, and point to this State as indicative of the value of such an institution. A Tacoma paper says: "The work now being done under the State Mineralogist of California, and in fact all the work done so far in that State by the State survey or State Mining Bureau, has been the greatest and most remunerative advertising which has ever been accomplished there. The annual report and the bulletins of recent publication are of the greatest value in advertising the mineral resources of that famous State." These and hundreds of other utterances are respectfully commended to the shortsighted statesmen or countysmen at Sacramento, who seek to destroy the only institution the California miner has, in the name of "economy."

SENATOR TELLER, of Colorado, has introduced a bill in the Senate to suspend that portion of the U. S. Mining law requiring the annual expenditure of at least $100 on a claim for the current year—a repetition of the "suspension of assessment" of '93 and '94. The PRESS favored such a law in '93, the first time it was proposed, it being represented that there was so universal a demand for such relief that it was in every sense a public measure. There was some opposition to it then, but it went through. In '94 it went through again, though the PRESS and other mining papers pointed out how one-sided and detrimental the result of the suspension was. It is only by results that laws or their suspension can be judged. The "suspension of assessment" has had a trial. It is a failure in the original intent, a detriment to the development of mining industry and an injury to every man who is in earnest as to the working or life of his claim. For these reasons the PRESS opposes any suspension of assessment, believing such legislation to be against the real interests of the real miner. It would be against public policy and the public good to repeat in '95 the mistake of '94 and '93.

The Debris Commission.

From the time of the adverse decision till March, '93, hydraulic mining in California, except on tributaries of unnavigable streams, was under a ban. After years of effort and untiring struggle a bill was passed by Congress two years ago legalizing hydraulic mining in this State and prescribing the conditions and requirements under which it could be carried on. The bill which thus legalized the rehabilitation of one of California's greatest industries was a compromise measure, and, as passed, was not wholly satisfactory. Some of the hydraulic miners, from the tone of court decisions in '92, thought they could get along without such a law. Some of the valley residents wanted to see no dams, no hydraulic mining. But the passage of the law was of great benefit to all classes alike; it settled a long continued dispute; it made easy way for the working of the mines; it allowed renewed output of gold; and, above all, it put the control of the matter into the hands of men above local, sectional or personal prejudice—men skilled, impartial and exact, unbiased and independent; the provisions and enforcement of the law being vested in a U. S. Government Debris Commission, composed of distinguished members of the United States Engineering Corps.

In '88 U. S. engineers made a report to Congress on hydraulic mining in California; on the basis of that report the Cal. Miners' Association worked for the passage of a bill, and when the act of '93 passed, United States engineers thoroughly familiar with the subject were appointed. Col. Mendell, Lieut.-Col. Benyaurd and Major Hener, members of the original Debris Commission, were constituted the United States Debris Commission with power to interpret and enforce the law regarding hydraulic mining in this State.

It may be said here, parenthetically, that shortly after the passage by Congress of the bill creating the U. S. Debris Commission, the Legislature of this State passed a bill authorizing the Governor to appoint a State Debris Commissioner, and appropriating $250,000 to be used in the construction of restraining works for the purpose of restraining mining debris, such appropriation, however, not to be available till Congress appropriate at least an equal amount. Gov. Markham appointed a State Debris Commissioner, but the failure or neglect of the general Government so far to appropriate money for the purpose indicated has made the State appropriation inoperative.

The State and general Government having thus been formally and almost unanimously committed to the policy of rehabilitating hydraulic mining in the State, the work began. The gentlemen comprising the board were given in such appointment considerable extra work, without any increase in compensation. After some correspondence with the Secretary of War, and it being apparent that the appointments were not civil commissions, but under the head of "army regulations," the Commission organized June 8, '93, established headquarters, elected officers, and promulgated its rules. Though the additional duty was unsought, onerous and manifestly unwelcome, the members of the U. S. Debris Commission have promptly, cheerfully and indefatigably performed all duty pertaining to the position, and have done a great deal of hard work. The bill creating the Commission appropriated $15,000 for its maintenance. Out of this meager amount the Commission has paid its expenses since its creation; but though an appropriation has been suggested more than once by the Commission, none is forthcoming, and unless such appropriation is made by Congress the active work of the Commission cannot continue.

The matter has been referred to in the above to place the salient facts in the case before the public. It goes without saying that the Commission has been of material benefit to California. It is a continuous body, the act creating it places no limit to its duration, and the $15,000 appropriated was merely meant for its immediate and initial expenses. The $15,000 was manifestly intended to tide over temporary requirements, but the continuous financial needs of the Commission have evidently been overlooked.

Congress adjourns by limitation on March 4th, and if anything is done before adjournment it must be projected at once. The Cal. Miners' Association, to whose unremitting efforts the existence of the Commission is largely due, has barely time to effectively direct the attention of Congress through our State delegation to the possibility of getting an adequate amount in the general appropriation bill.

During '94 the Commission received over one hundred petitions for permission to resume hydraulic mining, about three-fourths of which were acted on affirmatively; the gold yield from those so reopened should aggregate over half a million annually. The one hundred petitions received do not represent one-fourth the number of hydraulic mines operating in the State when the Sawyer decision shut them down, nor one-tenth the number that can and will operate under the auspices of the Commission and by reason of its authority. While the Commission cannot perish or be abrogated except by Congressional action, yet without Congressional appropriation it would be powerless to perform the work assigned to it. This is a matter of such manifest importance to the mining industry of the State that it demands immediate and earnest attention.

California has always been modest, too modest, in its requests of the federal Government. In the thirty years between '48 and '78 California gave to the world $1,185,550,000 in gold; since then she has contributed $224,000,000 more. It would be simple justice for the United States Government to appropriate the meager amount required to properly and permanently place the hydraulic mines of the State in position to pour out a perennial stream of gold aggregating more than the thousands of millions already yielded; it would be in order to place for immediate use the $250,000 contingent upon which an appropriation of that amount for that purpose was made by the State, and it is certain that if the few paltry thousands needed to keep the Debris Commission up to its present high state of efficiency be asked for it will be promptly forthcoming. It is evidently more a matter of negligence than intent to withhold that has occasioned the present probability of a check to the usefulness of that body. No State in the Union has given so much or got so little.

On this topic U. S. Senator Perkins says: "We have not been fairly dealt with. In the dark days of this country, when we did not know whether our Government was to be maintained or not, it was the gold dug from the mines by California miners that maintained the credit of the nation."

Ex-Congressman Clunie says: "In war times, when the lamented Lincoln presided over the destinies of this great nation, he called upon California, which responded with millions of dollars taken from our State treasury and given to the nation, to be returned at the close of the war. I found that upwards of $3,000,000 had been advanced by this State for that purpose, and that not one dollar had ever been returned to this State. I gave a year's time to this; went over all the vouchers, and every public official that examined them agreed that they owed this State upwards of $3,000,000, not counting any interest. I prepared a bill; it was submitted to the committee, unanimously approved and reported, but the appropriations were already made up and it had to go over to another Congress."

That is as far as it ever got. The money is still due. Anything that California asks from Congress is but a small percentage of what is rightly her own. The United States concedes it owes this State $3,000,000, and has owed it for over thirty years. This is a question that transcends the limits of this article, but enough has been said to illustrate the necessity and justice of immediate appropriation for the support of the United States Debris Commission.

A DENVER paper says that the assayer in charge of the mint at Denver, to whom was assigned the duty of collecting the statistics of the Colorado production of gold and silver for 1894, in his report to the directors of the mint, places the production of gold at $10,616,400, and silver 23,748,000 ounces, which, at the average price of silver for the year—63 cents per ounce—was worth $14,961,000, the coinage value of the same being $30,704,500. The increase in gold production for the year over '93 was $3,000,000, which illustrates the great mineral wealth of Colorado and the unusual attention given to gold production. The gold statistics of California for '94 are not yet complete, but it is thought the aggregate will not be far short of $14,000,000.

Concentrates.

ANTIMONY ore is being shipped to this city from Havilah, Kern Co.

NEVADA COUNTY papers say the reported Osborn Hill-Orleans deal is off.

THE *Courier* says that inside of ten years Prescott will be a second Denver.

THE Bullion-Beck (Utah) mine declared another $25,000 dividend on the 5th.

A 100-TON CAPACITY SMELTING WORKS is to be shortly built at Allerton, New Mexico.

THE Gover mine, in Amador Co., is to be sold, and the indebtedness paid this month.

A. CARRIGAN, of Dunham, Carrigan & Co., is developing the Badger Hill, Nevada Co., mine.

E. B. GAGE is reported to have bought the Congress mine at Congress, Arizona, for $1,000,000.

E. BECKMAN, of Santa Barbara, is about to build a mill on the property at Bland, New Mexico.

UP to date Capt. Bradford, of Utah, and his wonderful new gold process have not materialized.

H. C. BOONE has bonded his mining claims at Carlisle, Arizona, to an English syndicate, for $80,000.

ONE HUNDRED MEN are employed at the Virtue mine, Baker Co., Oregon. The monthly output is $20,000.

SOUTH DAKOTA prospectors say that "every ore chute or deposit (other than gravel) has its vertical."

Two new gold quartz mills are talked of at Carr Fork, Bingham district, Utah, to be built as soon as weather permits.

THE Boston and Montana Co. propose to put up the largest quartz mill in the State—300 stamps—on their Mariposa county property.

THE West Fork Placer Gold Mining Company, Madison county, Montana, will expend $50,000 in development work in the spring.

WORK at the Giant King mine, near Washington, Cal., is reported suspended till the rock can be tested for its value by mill process.

A HARQUA HALA miner says: What we ought to do is to survey all our claims because things are getting badly mixed in this camp.

THE Lakeview Consolidated Gold and Silver Mining Company, Beaverhead county, Montana, has incorporated; capital stock, $500,000.

THE Alaska M. & M. Company, of Pike City, Sierra Co., has bought the Grizzly quartz claim and will work it in conjunction with the Alaska.

THE Cariboo Mining, Milling and Smelting Company, of Spokane, Wash., has increased its capital stock to $800,000 and declared an $8000 dividend.

PINACATE DISTRICT, Riverside Co., is reported producing from $30,000 to $50,000 in gold, and paying out for labor and supplies $10,000 per month.

THE *Record* hears that a half interest in the Tom Boy Gold Mines Company of Telluride, Col., is about to be placed with English capitalists at $750,000.

THE Argus Gold Mining Co., of Cleveland, O., have bought several locations in Snows canyon, Modoc district, Inyo Co., and propose building a 20-stamp mill.

THE total ore shipments, up to January 24th, from Kootenay, were 1302 tons, value $171,900. In Trail creek two mines are shipping at the rate of $150,000 a month.

CHICAGO MEN have bought the Mountain View mine, forty miles from Fresno, for $100,000. A 20-stamp mill, concentrators and complete chlorination plant will be put in.

THE fact that as depth is attained the Clear Creek, Colorado, silver mines are changing into gold mines is another illustration of the fact that "History repeats itself."

A MINING revival is reported from the Panamint mines, southern Inyo Co., which have been sold to W. Remsen, P. A. Graff and Y. D. Dechert, of New York city.

MINERS and others living at Picacho, on the Colorado river, have in public meeting organized and formed the old Picacho mining district, opposite Eureka on the Colorado river.

THE Spokane, Wash., Hydraulic Placer Mining Company have elected a new set of officers and will resume work on their ground near Murray, Idaho, at an early date in the spring.

JACK ROUSE, who with two partners located a quartz mine in the vicinity of the Alaska-Treadwell mine on Douglas island, Alaska, is reported to have been offered $75,000 for the property.

THE Jones Creek Mill and Mining Co. has incorporated at Crescent City with an $80,000 capital. J. McLaughlin, E. Courmesford, W. Smith, E. A. Work and P. Emetsburg are directors.

THE Pinon Mining and Milling Co. incorporated in this city this week with a capital stock of $20,000,000. W. M. Sent, A. K. Durbrow, J. F. Millner, J. Fay and W. C. Stadtfield, incorporators.

THE adobe bricks, of which an old building in Sonora, Tuolumne Co., was constructed, are being pulverized and washed in sluice boxes for the gold they contain. The *Democrat* says good pay is realized.

MR. W. G. RIFENBURG, of San Diego, is in the city buying machinery for his placer mines in southeastern Nevada, near El Dorado canyon. It will be freighted from Kingman, Arizona, 100 miles from the mines.

THE Evening Star Mining Co., of Grass Valley, are discussing whether to put in new and heavier machinery or cease development. The present indications in the mine warrant a continuance of work.

THE Silver Plume, Col., *Standard* reminds the local chroniclers that the sending out of exaggerated reports is not the best way to boom a camp. It may fool somebody for a time, but finally the camp comes to be regarded with suspicion, and if anything really good is found it is hard to convince the public that such is a fact. If the truth is not sufficient to attract attention it is better not to say anything.

THE Montana *Missoulian* asserts solemnly that "Montana produced $43,000,000 in gold last year." An alleged mining paper published in Los Angeles says Colorado's gold yield was greater than that of California in '94.

WITH favorable silver legislation Butte, Montana, would have in operation 300 paying mines. There are a great many mines being worked at present, but the larger portion of them are copper and gold properties.

THE statement of the San Diego correspondent of the Los Angeles *Times* that the Golden Cross mine had been sold for $1,000,000 is denied in Yuma, where it is said the mine is worth vastly more than that amount.

A COMPANY has been organized in Montana to work placer mines on the Yahk river. The company owns ground about half way from the falls to Snipetown and on a bar above the mouth of the Yahk on the Kootenai river.

THE Grass Valley *Union* says E. E. Matteson, whom it styles "the inventor of hydraulic mining," is an inmate of the Nevada Co. hospital. It says he was the first person to use a canvas hose and nozzle in hydraulicking gravel claims.

A CARLOAD of pig tin, amounting to 322 bars, passed through San Antonio, Texas, last Sunday, consigned to New York from mines near Durango, Mexico, and said to be the second shipment of tin ore ever mined on the American continent.

J. D. DE LAMAR is reported to have sold his mines in southwestern Idaho for $2,000,000 to Paris capitalists, the proceeds to be used in developing his mines at De Lamar, Nevada, and aiding in the construction of the pending railway through Lincoln Co., Nevada.

THE Buttes mine, near Sierra City, is reported shut down on account of lack of water. Superintendent Thomas has given a crew of men a contract for $500 to bring the water in to the mine. There are about five miles of flume and one mile of ditch to shovel out.

THOS. JONES, of Henley, tells the *Journal* he can't keep enough mining location blanks on hand, from the constant locations made, since the discovery of the great porphyry dyke extending from the mouth of the Shasta river almost up to the Oregon boundary.

THE usually correct "Ores and Metals," of Denver, reports a find of platinum at Laramie, Wyoming, as "the first platinum discovered in this country." Platinum was long since discovered in this State, it being a not uncommon placer product. It has also been found in Oregon.

THE Yreka *Journal* says the miners at Cherry creek are prepared for ground sluicing as soon as the snow melts. They expect a good opportunity of day supply until late in the summer, by means of the self shooters, an automatic device for opening the taps when reservoirs are full.

AUSTIN & Co. of the blue gravel mine on Greenhorn creek, near Yreka, continue to take out from seven to nine ounces a day, and will do much better when the weather gets warmer, or warm rains occur to furnish sufficient water to wash the tailings. The total cleanup for last week amounted to $1300.

LAST Monday, while a cage was being lowered in the Crown Point mine, at Virginia City, Nev., the breaking of cogs in the pinion wheel of the hoist engine caused the wreckage of the entire hoisting plant, the cage and the cable dropping to the sump on the 1100-foot level. No one was hurt. The damage was between $2000 and $3000.

THE usual order of things is reported reversed at the Sunny South mine, Placer Co., where the white miners accepted a recent cut in wages from $3 to $2.50 per day, while the Chinese, who were cut from $1.75 to $1.50 laid down their tools and refused to work at the reduced wages. Supt. Power is putting on white men in their places.

COMPARING results of operations at the Silver King and the Number One, Ainsworth camp, the *Tribune* points out that, with the expenditure of labor equal to 14,600 ten-hour days, the Silver King shipped 700 tons. From the Number One, with 1200 ten-hour days' work, an equal amount has been shipped. The Silver King had a superintendent from West Africa. The Number One is managed by a Mr. McVicar.

THE Jones & Ready mine, adjoining the De Lamar (Idaho) mine on the north, was sold this week to the McKinley Bros., of Wisconsin, for $80,000. The purchase includes the Jones quartz mill and site located below the De Lamar mill on Jordan creek. The new owners will put thirty men at work opening up the mine and getting the mill in shape to work the ore.

THE report of John Hays Hammond on the gold fields of Mashonaland and Matabeleland is to hand. It is comprehensive, and, though conservative, inclines to be favorable. The conclusion is that wealthy corporations would do well, but that individuals would not prosper. Everything is cheap but transportation, and railroads now heading for that region will soon make that cheap, too.

THE placer ground of eastern Oregon covers the greater portion of Baker, Grant, Union and a part of Malheur and Umatilla counties. The same districts are also seamed with veins of gold-bearing rock of greater or less value, but a large number of them are sufficiently rich as to be profitably worked. Regular deposits are made weekly from some of the mines, and it is an unusual thing to find the Baker City bank without several large gold bricks on its counters.

OF a published total of 331 mining companies representing a capital of $103,000,000, sixty-eight were controlled in Great Britain last year. Eighteen companies, representing £1,221,500 were registered for operations in Europe: 10 in Asia, having £932,007 capital; 79 in Africa, with £6,230,780 capital; 25 in North America, with £1,685,700 capital; 18 in South America, with £2,269,220 capital; and 113 in Australia, representing £7,439,014 capital, the latter country claiming over one-third of the total British capital so represented.

THE Lemhi Gold Mining Company, with a capital stock of $5,000,000, divided into 500,000 shares of the par value of $10 each, has filed articles of incorporation in Salt Lake. The board of directors under oath—a formality exacted by law—testified that they believed the Grand Central, Annex, Shylock, Lemhi, Silver Queen, Gold Creek, Crown Point, Gold Bed, Away Up, Gold Bug and other claims in Lemhi county, Idaho, upon which the capitalization is based, were worth now and prospectively that much. The officers of the company are ex-Congressman G. W. E. Dorsey of Nebraska, president; D. D. Johnson, vice-president; L. A. Benton, secretary and treasurer. These, with S. J. Weigel, T. P. DeGroat, W. H. Goss and Truman Schenck, constitute the board of directors.

A MEMBER of the London Stock Exchange writes to the New York *Financial Record* as follows: "The space formerly devoted to the American market is deserted, but we are better off than the brokers of the New York Stock Exchange. We have a new pack of cards to play with—South African properties. At this moment the game is lively and, so far, profitable to brokers and customers. Can you not give us a new pack of Americans? The old one is worn out."

THE Pilot Bay, B. C., smelter burns thirty cords of wood a day, and soon expects to use eighty cords when the charcoal kilns are in operation. Six months ago the partially completed smelter buildings at Pilot Bay were surrounded by the wreckage of the high water of last June. A 200-ton concentrator is in operation, four roasters have been built and two of them put in use, an 80-ton stack is almost ready to be blown in, machinery is being placed in position for sampling works, and every barge on Kootenay lake is being used to transport either ore or fuel.

THE following are recent incorporations: The Lake View Consolidated Gold & Silver Mining Co., at Dillon, Montana, capital stock, $500,000. Slocan Surprise Co., of Chicago, Ill., at Victoria, B. C.: capital stock, $225,000, with shares at $100 each. Bellingham Bay Hydraulic Mining Co., at Fairhaven, Wash., registered at Victoria, B. C.: capital stock, $30,000, with shares at $50 each. Yahk River Placer Mining & Development Co., at Phillipsburg, Montana; capital stock, $800,000. Incorporators, John Ainslie, Chas. Glass, Dr. I. W. Power, T. T. Grant, Vernon Curtis.

IT was recently claimed in the San Francisco *Chronicle* and Colfax *Sentinel* that Fred Howell of the Hidden Treasure mine, in Placer Co., was and is the oldest miner in the State, he having mined right along for sixty years. A brief but interesting biography was given of the aged gentleman who has spent sixty years in the active work of mining. But there are fifty-six other counties to hear from; and calling the roll—Alpine, Alameda—we come to Butte, which comes up with a miner named Joseph Glines, who has been mining sixty-one years. He is at present developing the Willard mine near Magalia. Mr. G. was born in Marietta, Ohio, July 19, 1815. In 1834 he went West in company with his father to the lead mining district in northwestern Illinois, Jo Davies county, and commenced his mining career near the town of Galena. After spending a few years there he went to a mining section in what was then Michigan territory, but is now the southwestern corner of Wisconsin, where he continued mining till the spring of 1850, making sixteen years. On the 23d of May of the last-mentioned year he left the town of Shullsburg, Lafayette county, with the pack train of Capt. Al. Townsend, who struck the gold mines at Rough and Ready, Nevada county, in 1849, returned to the States and crossed the plains again in 1850. This company reached Grass Valley, in Nevada county, then a mining camp of three houses, on the 9th of September—Admission Day. He spent twenty years at mining in Nevada county and twenty-five to date in Butte, making sixty-one years in all. He lived a widower thirty-eight years, but last fall married again. If there be any older miner than he in the State, it is not noised around much.

Personal.

STATE MINERALOGIST CRAWFORD has returned from a trip to Placer county.

C. M. KENNEY has been elected general manager of the Pacific Rolling Mills.

H. W. CLINTON, a brother-in-law of Adolph Sutro, is to have the superintendency of the Sutro tunnel.

JOHN A. KIRBY, a practical miner, has been given the superintendency of the Bullion-Beck, Utah, mill and mine.

F. B. PLEBY, a mining expert, is visiting Methlahtkatla and other Alaskan points in the interest of Senator Jno. P. Jones.

DR. G. M. DAWSON, C. M. G., F. R. S., has been appointed Director of the Geological Survey of Canada, in succession to Dr. A. R. C. Selwyn, who has been superannuated.

IT is the paper that is most carefully read that gives the advertiser the best returns for the money expended. There is probably no paper in the country that is more closely read by its intelligent subscribers than this one, and in every mining community in the west half of America thousands of readers weekly note every line in its columns before filing it away for future reference. Since the recent revival in gold mining in this and other States, the already large number of readers has greatly increased, and the increasing number of inquiries daily received regarding matters, new and otherwise, discussed therein, evinces the interest felt throughout the mining world in the MINING AND SCIENTIFIC PRESS—the oldest of its class in the nation.

THE singular discrepancies in bids for work, so often noted, appear in electrical as in other lines. Recently the Interior Department at Washington, D. C., called for bids for the construction of a telephone system. A Philadelphia company bid $2,996; its instruments made an average of 97½ per cent in the test. There were six bids. A Chicago company, whose instruments made an average of 95 per cent, got the contract, its bid being the highest—$5,565.76, nearly twice that of the Philadelphia company.

The Great East Lode of California.

Written for the MINING AND SCIENTIFIC PRESS by W. H. STORMS.

All are familiar with the term "mother lode" in Californiа. It is generally understood to comprise all of those mines extendiug from the vicinity of the old town of Bridgeport, in Mariposa county, in a direction somewhat west of north entirely through Mariposa, Tuolumne, Calaveras and Amador couuties, and extending into El Dorado. The principal points along this great mineral zone are the Pine Tree and Josephine mines, uear Bear Valley, Coulterville, Jacksonville, Jamestown, Robinson's Ferry, Carson Hill, Angels, Sau Andreas, Jackson, Sutter Creek, Amador City and Plymouth. These points are directly on the line of the so-called "mother lode," and will serve to assist in fixing the geographical location of other mines to be referred to.

The "mother lode" has a remarkably straight course, as a glance at the State map will prove. Lying to the eastward of the "mother lode," at distances varying from five to fifteeu or more miles, is another gold belt second only to the more famous "mother lode" in importance. The course of this east lode is also remarkably straight. Its mines are disconnected, it is true, and therc is no great dike of ankerite to distinguish it throngh county after county, yet there is a persisteuce in the manner of the occurrence of shoot after shoot in rocks of distinctly different character.

Iu Mariposa couuty the east lode is about fifteen miles east of the "mother lode." Opposite Coulterville it is twelve to thirteen miles distaut. At a point east of Jamestown the distance is about ten miles. When opposite Angels the east lode is eight miles from the center of the "mother lode," the mineral belt of the latter beiug here three miles wide. Iu Amador county the east lode is but six miles distaut from Jackson.

Thus it will be seen that the east lode has a more westerly trend thau the "mother lode," and apparently would intersect it. Before this convergence occurs, however, the country is so much disturbed in El Dorado as to reuder it impossible at present to say whether these two great vein systems converge or not. They are not known to, at any rate.

The mines of the east lode do not occupy a single great fissure, but along a certain line of disturbance we find many fissures, all of which have a decided branching teudency. The great veins send out many spurs, chiefly into the hanging-wall, though they often occur in the footwall. Great movement, which has resulted in well-marked striations, are common and prominent features of this belt. The chief and most striking characteristics of this vein system are their branching habit; the overlapping of the walls; the deep striation of the planes of the fissures, the grooves being sometimes mere scratches, at others a foot wide; and again they occur in great swells six or eight feet across; the crushed and broken condition of the rocks adjacent to the walls; the frequent mixture of quartz and wall rock in the pay shoots; the occnrrence of massive qnartz free from these slaty inclusions and usually very low grade iu gold; and the universal presence of eruptive dike rocks with the fissures often in direct contact with pay shoots.

The general direction of the lode, as has been stated, is northwest, bnt the mines strike at all conceivable angles from east around to west, though most of them strike in a northwesterly direction. It should be noted also that these mines nsually conform with the *strike* of the enclosing slates, though not with the *dip*. The quartz from those mines which conform to the strike of the enclosing rocks (the slates) always coutains more or less slaty material and bears a marked similarity, but that from those fissures which cross the strike of the slates is usually more massive and easily distinguished from the former, and contains less of the slaty wall rock. This condition is also noticeable iu the veins of the "mother lode."

Where there has been great movemeut since the formation of the vein, the tremendous pressure resulting in crushing and granulating the qnartz, the rock from one mine can scarcely be distingnished from another. A brecciated condition is often fonnd in these veins.

The direction of the pay shoots may always be inferred from the striations on the wall. They almost invariably pitch in the direction indicated by the grooves.

Nearly all of those veins which strike north, and from there around to the east, are more massive thau those striking west of north. This is due, as has already been indicated, to the fact that the general trend of the formation is west of north. From a geological standpoint I consider the entire fissure system as one great lode, dne to a common orographic movement of the western base of the Sierra Nevada.

The fissures cut everything in their course—granites, slates, schists, diorite and diabase—and also, usually, the later acid eruptive rocks, which always accompany these veins. These light-colored dike rocks which cut through the older diorites and diabases, are found in the bottoms of the deepest canyons aud on the summits of the highest hills. They are all of the granitic type and range from a granite of very coarse crystallization (pegmatite), as in the North Fork mine in Tuolumne county, or at the Dead Horse mine near Summersville, to grannlite in the Bandarita, east of Coulterville, and felsite at Hite's mine and in the Keltz, north of Sonlsbyville.

The geological indications all point to the fact that these acid eruptives were first injected into the planes of weakness caused by a stress and movement of the mountaiu masses, aud that the formation of the veins was altogether subsequent to this period.

A continued movement of the rocks on the fractured planes formed the couditions so essential for the infiltration of mineral waters bearing the silica, gold and several sulphide minerals. These movements were doubtless continued from time to time during the formation of the veins, and in mauy places long after their formation was complete, unless, indeed, as some suppose, they are still forming. Perhaps they are. I am not prepared to dispute it, though I doubt such being the case at any point above the drainage level, by which I mean that level where snbterranean waters pass upward from pressure and not downward by gravity.

The masses of quartz present several phases of formation. The frequent occurrence of a banded structure (ribbou rock) suggests that the rim was formed largely by the infiltration of mineral solutions into a mass of foliated, crushed slate. In some cases this banded appearance may be due to the original structure of the slaty material, and in others to numerous parallel fissures occnrring side by side, bnt in the majority of instances it seems to have been occasioned simply by the slaty or schistose structure of the rocks forming the walls, this structure being still preserved.

Those portions of the lode occurring entirely withiu grauite are usnally more massive than elsewhere, though a banded structnre is also sometimes noticed in these mines. But I apprehend that in such cases the structure is due almost entirely to movement and pressnre.

There are occurrences of crystallized quartz in some of these mines, indicating that the vein was deposited in au opeu crevice. These cases are not common, however, on this lode.

The great masses of white quartz sometimes found containing no slaty or other inclusions, I am at a loss to understand, unless it be that the mineral solutions concentrating at these points from some unknown cause, resulted in a complete dissolution of the fractnred country rock and its entire replacement by silica. In other regions I have seen masses of snow-white quartz so large and free from all other material as to lead me to believe that they may possibly be of eruptive origin, altered somewhat—subsequently, no doubt.

The dike rocks, already referred to, occur in connection with every mine along the lode. By inquiry and investigation it was learned that almost invariably the near presence to or direct contact with a dike resulted in an enrichment of the ore. I cannot doubt that these dikes have had a beneficial effect on ore deposition. Just what the nature of this influence has been, it appears difficult to determine. This question has already been the subject of much disenssion, and well-known authorities are, as yet, far from an agreement. Many believe that the minerals of veins and ore deposits are derived directly from neighboring eruptive rocks; others contend that these dikes are simply channels along which mineral waters have found a passage, aud that the solutions have deposited their contents in the places best prepared for their reception. It is a well-known fact that valuable ore deposits do occur where there are no dikes, as in the Missouri lead and zinc mines; but there are fissures, evidently having great depth, through which the mineral solntions asceuded.

We know of profound faults which must extend to very great depths, aud yet no ore deposits occur aloug the plane of fracture. Still, this would not disprove the hypothesis that mineral solutions came up from great depths aloug chaunels afforded by the fissure planes of an eruptive dike. There can be no doubt of the deep-seated origin of the dike rock, while there is doubt as to the depth to which the most profound faults may extend.

The influence of dike rocks upon ore shoots and pockets shonld be more carefully studied by miners themselves, as a more complete knowledge of the relation of ore bodies to the adjacent rocks may lead to many important results. By comparison I find that many of the most valnable mines of the past and present in this State are accompanied by dike rocks of marked similarity, not only on the east lode, but elsewhere.

The principal mines on the east lode are the Hite, Ferguson, Comet, Kanaka, Bandarita, Hasloe and Red Clond, in Mariposa county; the Bnchanan, Consuella, Huuter, Dead Horse, Eureka, Louisiana, Puerto Fino, Laura, North Star, Soulsby, Black Oak and Keltz, iu Tuolumne county; the mines of the Americau camp, Collierville, Sheep Ranche, Railroad Flat and West Point district, in Calaveras county; and those at Weiland, Pine Grove and the belt east of Volcono, in Amador couuty.

The total production of these mines I do not know, but it is a large amount, considerably exceeding $10,000,000.

The mines in the vicinity of Murphys, in Tuolumne county, are not properly on this belt, but are situated between the "mother lode" and the east lode. The Confidence mine and those near it, in Tuolumne county, lie east of the east lode; and there are many others in this eastern belt, lying between the east lode and the Sierras, of which little is known. Attention is being directed to that region, and these prospects, so long idle, are likely to take a prominent place in the active mines of the State.

There is now considerable activity all along the east lode, and this is destined to continne with encouraging and substantial resnlts.

The Comet mine in Devil's gulch, in Mariposa county, is a new enterprise on this lode. Several old mines are being reopened near Summersville, and also in the vicinity of Volcano.

On the Choice of a Career.

The profession of a mechanical engineer, to the uniuitiated, holds forth big inducements, and the young man who starts in college works his way along, graduates and nine cases in ten is assigned a positiou over the drawing board. Draughting, in its higher forms, is one of the most interesting subjects in existence, especially when other conditions are such as to promote the interest. It rests in the hands of the draughtsman whether the machine will be pulled down several times in order to correct mistakes, and in many cases whether the machine goes to the "scrap heap" or is shipped away a success.

One of the first couditions of good work is a comfortable place to work in. How many concerns in the country, manufacturing machinery, have even a decent place for their draughtsmen? The average is a dirty, badly ventilated, dimly lighted room without proper heat in the winter, frightfully hot in the summer; yet educated men are supposed to go there, use their brains, avoid mistakes, and rush through their work, turning out machine after machine, having a highly heated gas jet within two inches of the top of their heads; yet, invariably, if a man be taken ill—may be from standing in a draught strong enough to blow a tracing off a table—he is "docked" for the time he is away. It would be interesting to obtain a list of the firms that give their men a holiday without taking a day's pay from their already magnificent remuneration.

The draughting profession at present is a delusion and a snare, as regards the general machinery business, and the old plea that a man is "learning something" is no excuse for a firm paying its head draughtsman $18 per week. A man can keep on "learning something" until he is ready to die of old age, living on small pay. So many people say, "It is so hard to find a good draughtsman." Why, most men who arrive at the age of thirty either get away from the board or out of the business, driven to desperation by the "learning something" basis of pay. Suppose, through nothing but competency, he secures a very remunerative position. Invariably he is obliged to isolate himself from civilization in some small country village, or in some swamp, where many concerns locate their works; and once there, he stands a good chance of staying there unless he is "fired." Some companies, heaven bless them, realize that draughtsmen are human beings, and a roll of honor should be framed for them. There shonld also be a list of firms that should be avoided by any man who has any regard for fair treatment and health. Long hours, rushing, driving work, contemptible pay and hopeless prospects take away all interest in the profession, which is certainly on the decline.—"Condensation" in Scientific American.

Automatic Water Tanks.

Dnring the past year, says the *Railway Age*, the railways of the United States paid $7,000,000 to maintain the 10,000 water stations in this country. This expense, it is claimed, will be saved by the automatic tank now coming into use. This tank is actuated by steam from each locomotive as it stops for water—steam that would otherwise be wasted, as almost every locomotive while taking water blows off steam representing more than sufficient power to elevate a tenderful of water. There is nothing to do in operating the tank but for the fireman to turn on steam, which starts the flow of water into the tender, and to shut it off when the tender is filled. The next locomotive may be brought to the tank at once, a full supply of water being always ready.

THE *American Shipbuilder* says the large shipbuilders, Harland & Wolff, Belfast, Ireland, who built the Majestic and Teutonic, pay riveters $7.54 per week; patteru makers, $8.27 per week; platers the same; and fitters $6.57 to $8. More than twice these sums are paid in this country to the same trades, and it is no wonder that merchant ships are built abroad instead of this country, with snch a wide discrepancy in the cost for labor.

The Lick Statuary.

One of the newest and most notable of the city's attractions is the Lick Statuary in front of the City Hall. It is the result of a provision in the will of James Lick by which $100,000 has been expended to commemorate notable features of the history of California. Of twenty-eight competing designs, that of Frank Happersberger was chosen, and the engraving shows its form and characters.

The monument consists of one central, spherical structure of Rocklin granite, 47 feet in height from the ground to the tip of the spear of the bronze figure on top. This center structure is approached by a flight of steps, and wing-like pedestals extend from the main structure on four sides. The main figure, and the one that first attracts the eye, is a bronze figure of Eureka, 12 feet 6 inches high and weighing 8000 pounds. The four side pedestals each uphold bronze figures of heroic size. Upon and around the center structure are bronze alto-reliefs, typifying California productions, and portraits and names of men who have made California history. The four lower pedestals each support elaborate bronze designs representing mining, commerce and agriculture.

The south group, and the most prominent, in many ways, represents the miner, the characteristics of which are well portrayed in the illustration. The discoverer of sundry gold nuggets is showing them and where he got them from to his two companions, who seem imbued with the realization of what that gold discovery meant to California and the world. The statuary constitutes one of the sights of the city.

THE LICK STATUARY RECENTLY COMPLETED IN SAN FRANCISCO.

Times Have Changed.

But a few years ago, says the Cosmopolis, Wash., *Enterprise*, all that was necessary to coin money in the manufacture of lumber in western Washington was to place a mill almost anywhere, get a crew of loggers and mill men, and begin operations. There was no necessity of hunting a market for the product, as customers were anxious and waiting.

But times have changed. The home market has ceased to be much of a factor, and the strong competition has reduced prices so that only the mills that are favorably located and equipped with the latest improved machinery are in the race. A good location is absolutely necessary, if success is desired; and such a location must include a convenient and abundant supply of suitable logs, and ample facilities for shipping both by water and rail.

Eastern buyers of Washington lumber demand the best grades, either of large dimensions for bridge building or of the smaller dimensions. It is impossible to pay the freight on common lumber and sell it in the Eastern market. The price the consumer would have to pay would be out of proportion to that asked for common lumber brought from other places, and there would be no sale for common lumber from Washington.

Every mill when running turns out a certain percentage of low-grade lumber, for which a market must be found. With the local demand limited and the East most effectually barred, recourse must be had to a market opened to the lumbermen of this State by the use of deep-water vessels. In putting up a new mill, then, or moving a plant that has been in use, the promoters of the business enterprise would select for a location none other than a seaport town. They want a point as near their common-lumber market as possible, a point where the best harbor and docks can be had, a point where all the logs needed can be obtained easily and safely held until wanted for use, a point connected with the great railway systems of this country.

As an indication of how the slave trade survives in Africa, it is stated that last summer a caravan of 10,000 camels and 4000 slaves left Timbuctoo for Morocco.

Diamonds.

The El Dorado *Republican* of recent dates has two accounts of the finding of diamonds in that vicinity. The more recent is as follows, clipped from that paper of issues Dec. 6 and 20, '94:

FOUND A DIAMOND.

Bert Carpender, son of Justice W. F. Carpender of this city, while panning some tailings from the deep gravel channels at Smith's Flat one day last week, found a very handsome and perfectly formed diamond, though not a very large gem. He picked it out of his mining pan after washing its contents nearly out. The stone weighs nearly two carats, and is about the size of an ordinary pea. The exact value of diamonds depends very much on the fancy of the purchaser, but this one is probably worth anywhere from $50 to $150, and Mr. Carpender does not appear to be anxious to sell it for $100, as he thinks of having it set in a ring. A number of other diamonds have been found in the same vicinity, the most valuable specimen being sold for $300, although it is now believed that it was worth five times that price.

ANOTHER DIAMOND.

We recently announced that Bert Carpender had found a diamond at Smith's Flat while working some tailings from the ancient river channels passing under this place. This week he found another in the same place. The first weighed nearly two carats, and the last more than one and a half carats. His unusual good fortune has attracted considerable attention, and may lead to further discoveries, as so many diamonds have been found in this locality that it seems probable that they are more numerous than has been supposed. Hundreds of them have been probably crushed in the gravel mills, as fragments have been detected in the tailings. It seems probable that the origin of these diamonds is in the lava which caps all the ancient river channels in this part of California, for, except in color, it appears similar to the volcanic cement in which they are imbedded in South Africa.

This is not the first time that attention has been directed to the fact that diamonds are a California product, though a rare one. It may be that some prospector may strike a diamond mine. Inquiries are occasionally made by placer miners and diamond prospectors, for some simple way by which, without the possibility of mistake, they can tell when they find diamonds in the working of their placers. The books on the subject of precious stones do not give plain directions for that purpose. One often hears of stones, supposed to be diamonds, being sent to London, Paris and other places for determination, denoting that there is much attention being paid to this matter. Melville Attwood, F. G. S., has been in the diamond mines of Brazil, and says:

"I think that the gold and diamond placers of Brazil, like those of California, may properly be divided into three classes:

"1st. The surface washings and the ravine diggings, which have derived their gold principally from the degradation or breaking up by atmospheric and aqueous agencies of the croppings of the auriferous veins. The gold found in these placers is mostly angular, with pieces of quartz adhering to it. This class, to a certain extent, has been the most important of the three, as nearly all our richest quartz veins were discovered by working them. For instance, in the Grass Valley district, at Rhode Island Ravine diggings, the first gold vein was uncovered—the Gold Hill. Then the Boston Ravine diggings, the Massachusetts Hill mines, the Allison Ranch diggings, the Allison Ranch mine, the Lamarque diggings, near the north branch of Wolf creek, which uncovered the Eureka, Idaho, etc.

"2d class consists of the recent river beds, from which the water has been diverted, and the present river beds. In this class most of the Brazilian diamonds are met with.

"3d class, the ancient river beds, in which diamonds are also found.

"The Brazilian miners distinguish the various diamond placers by the following names: Grupiara, an alluvial deposit whose surface shows it to be the unused bed of a stream or river; burgalhao, small fragments of rock bestrewing the surface of the ground; easealho, fragments and pebbles of quartz, or rock and sand mixed with clay, forming the bed of a river; takoa carza, which consists of the above materials cemented together, forms a conglomerate mass. All, however, are known by the generic name of 'Cascalho.'

"The diamond prospector's outfit should consist of a light pick, a shovel, and two riddles, one having three-fourths of an inch apertures and eighteen inches in diameter, the other having eight holes to the linear inch; a miner's wallet, which is a bag four feet eight inches long by eighteen inches wide, with an opening in the middle—it can be carried over the shoulder or used as a saddle-bag, and in it a miner can pack forty pounds or more of gravel for a long distance; a tub for washing the gravel in—this may be got by cutting a wine or beer barrel in two (a rubber bath-tub will also answer the purpose); a piece of rubber cloth, to be used for sorting the gravel on; a watchmaker's lens of two powers, fitted into a spectacle frame; and a placer miner's scale of hardness, consisting of fragments of diamonds, sapphires and quartz, mounted at the ends of pencils. This outfit, with the scale of hardness, can be obtained of John Taylor & Co., San Francisco. The scale of hardness can be easily made by taking the rubber from the end of a pencil and filling the space with lapidary's cement, which melts at a very low temperature. Warm the fragments of diamonds or sapphires over a small spirit-lamp, and, while hot, insert them in the cement. By wetting the fingers and rubbing the cement, it can be molded into any shape desired, and, when cold, it will be as firm as if soldered.

"The sample of gravel to be examined must be first put into the coarse riddle and that fastened above the finer one. Then immerse both riddles in a tub of water, and, with a half-rotary motion, wash all the fine gravel into the lower one, the dirt and sand passing through into the tub. Then throw away what was collected in the coarse riddle, unfasten it from the finer one, immerse the latter in the tub of water, and use a jigging motion till all the heavier portions of the gravel have settled at the bottom. Continue the jigging, and by raising the riddle a little at one side you can get all the gravel to the opposite one. Then, with a very quick motion, turn the contents onto the sorting cloth or board, which should be placed near the tub. The heaviest gravel will then be at the top, and can easily be examined and tested. Take the pencil with the fragment of diamond mounted at the end of it, and, pressing lightly, try to scratch the suspected stone, at the same time looking at it through the lens. If no mark or scratch is found upon it, it must be a diamond, no matter what the *shape* or *color*.

"The fragments of diamond may be protected from injury by the metal covering used to cover the sharpened end of pencils. In Brazil, as yet, no mines have been discovered like those in South Africa, such as Kimberly, De Beer's, Du Tort's Pan, and Bultfontein, where the diamonds may be said to be found *in place*."

E. I. Dunn, in a paper read before the London Geographical Society on the African diamond mines, says: "That the old mines are 'volcanic pipes,' and that they have burst through these carbonaceous shales, is evident. Is it not reasonable to infer that the carbon, indispensable in one form or another to the formation of the diamond, was supplied by these shales?"

The chances are good that we may yet find in California one of these "volcanic pipes."

John G. Brady, of Alaska, proposes to explore Mount Edgecombe with a diamond expert and search for diamonds, which are thought to exist there.

Late last fall a hunter and prospector brought in some brilliant-looking lava ashes to Sitka, and showed them to Mr. Brady. The latter sent them to an expert in San Francisco, who returned word that an investigation should be made at the earliest opportunity. The contents of that letter contained astonnding information—pumice stone and scoria had all the elements for the presence of diamonds. Mr. Brady has perfected plans to reach the extinct crater of Mount Edgecombe, as soon as the snow and weather will permit.

For many years mineralogists have scrutinized the sides of Mount Edgecombe with a professional curiosity, because the lava scoria, ashes and pumice stone lead these men to conjecture that perhaps the conditions are favorable for the lodgment of the treasures for which Kimberly, South Africa, is known the world over.

The diamond is one of the things that the public is never tired hearing about, and is ever anxious to see, discuss, and, above all, to possess; but few have any idea of the tedious and laborious process by which the precious gem is mined and brought to the light of day. At the Kimberly mines all the entrances are rigidly guarded, and only the written permit of the manager will enable the visitor to descend the huge shaft which pierces the working level, say 1000 feet below. In the tunnels of the mine, which are about seven feet high, the miners are hard at work drilling holes in the adamant ground with a large crowbar, which they use with both hands. After making six holes each, which may take three hours, or six, or longer, according to the hardness of the stratum they are working in, they are allowed to retire to their homes in the compound and rest for the remainder of the day. Dynamite cartridges are placed in the drilled holes and exploded, and the blue ground which has been dislodged is shoveled into trucks, each of which holds a ton, run along the level and taken up the shaft. It is taken in large lumps as hard as granite to "the floors," where it is spread out and left from three to six months to be pulverized by the action of the sun, air and rain, a steam harrow being run over it from time to time to assist the process of disintegration.

In due time it is taken to the washing machine, the work of which is to sift out all the light deposit, called "tailings," in which no diamonds are found, and to clean the "ground," which is then placed in a hopper and carried by revolving buckets to the top of an elevator, whence it is dropped into a cylindrical pan. As the pan is rotated water is thrown on its contents, and the mass is chipped and sliced by iron knives, the light mud overflowing in the center, and the heavy deposits containing the diamonds passing into a pulsating receiver, from which it is graded into three different sized sieves. Water is then pumped through the bottom and the light deposit is forced over the top, the heavier substance falling through the sieves. It is then passed by means of valves into tubs, and the important work of searching for the diamond commences. Four times do the searchers examine every particle of the material, and so carefully and thoroughly is their work done that it is said that a half-carat diamond might be mixed with a couple of hundred-weight of earth in the hopper at the upper end of the sifting machine, with perfect assurance that it would ultimately come into the hands of the sorters.

Such vast quantities of gems are consumed in this country that the United States Geological Survey has thought it worth while to prepare a monograph on the subject, which will soon be issued.

The fact has been established that the supposed diamonds found in meteorites near the canyon Diablo in Arizona are actually such. This is a matter of profound interest, indicating as it does that such stones exist on other planets. Some authorities assert that diamonds, like coal, which is so nearly of the same chemical composition, could not possibly come into existence without previous vegetable growths to generate their material. For this reason they infer that the finding of the gems in the meteorites proves that there must have been vegetable life in the place whence the meteorites came. If there was vegetable life there is a fair presumption that there was animal life also. All this may be untrue, but it affords the first guess glimpse ever obtained into the greatest problem that mankind has attempted to handle, namely, the question whether life exists in other worlds than ours.

It seems strange to take a couple of ounces of charcoal in one's hand and to consider that one is handling the pure material of the diamond. If one could transform into crystalline form, he could sell these few pinches of stuff for $1000 perhaps. No wonder that chemists are eager to discover the secret of effecting this change. To assert that they will never learn how to make crystals of carbon would be absurd. By means of the voltaic battery real diamonds of almost microscopic size have been deposited upon threads of platinum. But, even if a successful process should be discovered, it might be that the cost of making a diamond by it would be bigger than the price of a stone of equal size and purity from the mines. One recalls the experiments of Professor Sage, who turned out gold pieces in his laboratory from gold extracted from the ashes of certain buried vegetable substances. The result was beautiful, scientifically speaking, but the expense of making in this way one $5 piece was about $25.

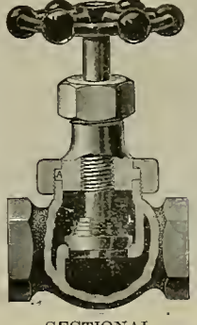
The value of rough gems of all sorts produced in this country in 1894 was $47,000 less than the output for the year before, amounting to only $237,000. The decrease was mainly owing to the industrial depression. The precious stones of the United States are sold in large part to tourists, who purchase them as souvenirs of localities visited.

Under date of the 1st inst., writing from Cripple Creek, Col., Mr. Alfred H. Hale, regarding a recent article entitled "African Diamond Mines" and the "Law of the Dutch Republic," calls attention to the fact that the Kimberly mines are situated in Cape Colony and are governed by the laws of that country. One can readily see how strange it would look were a person who has spent some time in traveling through the United States to locate Denver, Col., in California.

Some of the South African diamond mines are situated in the Orange Free State, but they only produce about seven per cent of the diamonds of the country.

Lunkenheimer's Regrinding Valves.

We present herewith a view of Lunkenheimer's regrinding globe valve, which possesses some features of special merit. Instead of the hub being threaded direct to the body of the valve it is merely fitted into it plain, and rests upon a flange which fits upon the upper edge of the opening, as shown in annexed cut. The hub is then secured by a nut which fits over the flange, and is threaded to the outside of the body of the valve. The result of this arrangement is that the valve can be reground at any time with the greatest facility, because all that is necessary is to loosen the nut, remove the hub, place a little sand and soap under the disk, and replace the hub, leaving the nut loose so the hub is free to turn with the stem during the re-grinding.



SECTIONAL.

A piece of wire or nail is passed through a hole provided for that purpose in the lower end of the stem of the disk, so that the disk will turn with the stem during the regrinding, which of course it does not necessarily do when the stem is in use.

The hub, being in place when the grinding is done, effectually centers the stem and holds it in proper place, so that the regrinding is done correctly. The valve can thus be readily ground while in position, and in many cases this does away with the necessity for breaking connections. The disk is also, of course, easily replaced when required. These valves (on account of having an outside thread and union connection for holding the hub to the valve shell) are always easily taken apart, as the hub will not

"cement" into the shell, as is the case with all other makes.

These valves are made of gun metal throughout, tested and inspected before leaving the works, and, as a proof of their superiority, are extensively used in rolling mills, refineries, on locomotives, steamships, and in the United States navy on cruisers, where the requirements are very severe. They are made by the Lunkenheimer Company, Cincinnati, O., who will be pleased to hear from any members of the trade. They have catalogues on brass goods for steam, which they will send to any address.

Dredging at Dayton.

(Continued from page 97.)

of Mr. J. C. Pierson of Sacramento as manager, and Captain Herman Davis, a marine engineer of note, to the position of superintendent, at Dayton.

Early in May, 1894, construction of the new plant was commenced from plans designed and drawn by Manager Pierson and Captain Davis, and all work was done under the immediate supervision and inspection of Captain Davis. Most parts of the machinery are original in design and were perfected for this particular proposition. The labor-saving devices are many and ingenious, and the writer found upon recent inspection that everything had been constructed in a very substantial manner. The plant consists of a large and powerful clam shell dredger, with a two-yard bucket, capable of easily handling from 1500 to 4000 tons per day of the river material. The amount varies with the conditions of the river bed and the proportion of rock, gravel and sand to be handled. The dredger is run by steam and has engines amounting to 150 H. P.

The second part of the floating plant consists of a barge 40x85 feet, on which is the machinery for screening the sand from rocks, gravel, etc. This barge also contains agitators, quicksilver traps, sluices and riffles for separating the amalgam, quicksilver and gold from the other materials. Power is furnished to the barge machinery by one double nozzle six-foot Pelton wheel of 80 H. P., working under 56 feet pressure, and one 4-foot double nozzle of the same make of 30 H. P. under the same pressure. Water for these wheels is conducted from the shore through a twenty-inch canvas hose attached to a conduit several miles in length which obtains supply from the river above.

The third part of the apparatus consists of the shore plant, a strongly built and double deck mill in which are a six-foot double nozzle Pelton wheel, a six-inch centrifugal pump, ten Woodbury concentrators on the lower deck, and twelve Warren concentrators on the upper deck; and above them, on a third deck, a distributor for the equal and even distribution of the pulp to the twenty-two machines.

The fourth part of the plant consists of the mill for working the sulphurets.

The general operation of the plant is as follows: The material is taken up from the river by the dredger, and dumped into the hopper on the end of the barge, where the large rocks, cobbles and gravel are separated from the finer sand by means of grizzlies. The finer material passes into revolving grizzlies that further separate the finer material from the coarser, and eventually it passes into a large revolving thirty-mesh screen, eight feet in diameter and eighteen feet long. All sand and pulp (which contains the sulphurets) fine enough to pass through this screen fall into a tank beneath, and pass into a centrifugal pump. The proportion of this pulp to the material hoisted from the river bed continually varies; sometimes seventy-five per cent of the material will pass through the final thirty-mesh screen, and at other times not more than ten per cent. The average is reported as about twenty-five per cent.

From the centrifugal pump the pulp is forced ashore through a pipe to a pump on the lower deck of the shore plant, by which it is elevated to the distributor on the third deck and from thence to the concentrators below. The barren sand, or tailings from the concentrators, are carried into the tail-race of the Pelton wheel that drives the shore plant, and by its current are carried away. The sulphurets are carried up and over the heads of the machines, and into their proper receptacles. The timbers of the shore plant are of 12x12 pine, and the whole is so constructed that as the work progresses up or down the river the shore plant may be moved in pace with the barge and dredger. Returning again to the barge; such material as enters the thirty-mesh screen and is too coarse to pass through its meshes is carried on and discharged at the tail end of the screen and the peculiar design of its helix. The material then travels onward and into a twelve-mesh screen, where it is again revolved and screened, or sized, and from there into agitators, thence through riffle sluices to the dump.

The distance through which the material travels and the process of continually extracting the barren sand and gravel affords conditions favorable for the recovery of quicksilver, amalgam and free material. This recovery begins the moment the material falls into the hopper from the dredger, and continues by various devices, including rillles. traps, sumps, amalgamating plates and settling pans, all so modified and distributed at various points as to suit them to the different conditions under which the free metal is presented for recovery.

In conversation with the writer Captain Davis said: "The working of this plant thus far has shown that each concentrator will handle from fifteen to twenty-four tons of this pulp each twenty-four hours, and the pulp or screened sand yields from three to forty per cent sulphurets. These sulphurets assay from $10 to $100 per ton. All of the factors are continually changing each minute of time that the machinery is running. For the short time in which the plant has been running since its completion, before the ice and cold weather stopped operations until warmer weather, the output was forty and one-half tons per twenty-four hours, averaging in assay value of sulphurets alone twelve hundred and sixteen dollars. The factors for free material, quicksilver and amalgam vary greatly. They vary from a few cents to several dollars per ton of the material hoisted from the river. The actual practical results can only be determined by longer practical work with the complete plant. Thus far the only actual known returns of quicksilver, free material and amalgam have been at the rate of twenty cents per ton for each ton of material hoisted from the river. In many places in the river the returns will go far above this figure, and at other places the returns for quicksilver, amalgam, etc., may go far below and amount to practically nothing."

The plant is at present closed down, on account of the cold weather, ice and snow, but the climate at Dayton will permit of at least 260 days' work during the year. Not including the men in the mills for working sulphurets, it requires eighteen men to run the plant day and night. These men are paid $2.50 per day for laborers, and $5 and $6 per day for experts in the different branches, the payroll amounting to some $2500 per month. Work will be resumed as soon as the weather permits.

If this be true of the Carson, why not equally true of the Sacramento and other rivers which receive the tailings of the various mines. A. C. ROBBINS.

MINING, MILLING AND SMELTING MACHINERY.

The Gates Ore and Rock Breaker

Gives a finer product than any other crusher made, adding by this means 25 to 30% to the output of any mill, beside saving the wear of the more costly machinery. It will reduce a given amount of ore at one-third the cost in wear of any other crusher on the market. It requires also much less power for the same amount of work.

The Gates Ore Crusher

Is now being adopted by the progressive Mining Companies in all parts of the world. More than 3000 of them now running.

The Pelton Water Wheel Company, General Western Agents,

121 Main Street, San Francisco, Cal.

Scientific Progress.

The Age of the Earth.

Scientists have differed greatly among themselves as to the probable length of time which the earth has taken to get into its present condition. Professor Guthrie Tait, having in view the rate at which the sun is supposed to be cooling, concludes that only about 10,000 years can be allowed to the earth since it was capable of retaining water on its surface in a liquid state. That, however, would presuppose a considerably longer period anterior to the other, when the globe was much hotter. Newcomb was disposed to fix the outside limit of the age of the whole solar system at 20,000,000. Clarence King computed, from experiments on volcanic rocks, that the whole duration of our globe had not exceeded 24,000,000. George Darwin figures out the interval that has elapsed since the molten mass composing the earth threw off the moon at 57,000,000. His calculations start with the influence of tidal friction in retarding the earth's rotation. Few estimates, however, have received quite the same respect from scientific men without a special theory of their own as Lord Kelvin's. Judgiug by the present temperature gradient in the earth's crust, as one goes downward, he thought that the whole mass could hardly have taken more than 100,000,000 years to eool down to its present stage.

Geologists, however, while not agreeing among themselves, have been disposed to demand still more time. Haughton made 200,000,000 his minimum; Sir Archibald Geikio's maximum is 680,000,000. In view of the very slow rate at which animal and vegetable species change, in the progress of evolution, biologists have favored the longer rather than the shorter periods here indicated; so that Lord Kelvin and some of his adherents have taken issue with those authorities as claiming altogether too much.

Such is this distinguished physicist's standing in the scientific world to-day that it has for years been considered rather audacious to question his conclusions on any point whatever. Nevertheless, within a few weeks, Professor John Perry, who occupies the chair of mechanical engineering and applied mathematics at Finsbury Technical College has made public his reasons for greatly extending our estimate of the earth's age. Like Kelvin, he assumes a sphere with a smooth surface, and a uniform heat of 7000 degrees Fahr. Taking it for granted, also, that the conductivity of the interior portion is the same as that of the crust, Perry gets the same answer as Kelvin, namely, about 100,000,000. But on the hypothesis that the internal mass had a higher rate of conductivity than the outer shell, this latest dissenter declares that a much longer time would be needed to bring the earth to its present state. On the basis of ten times greater conductivity within than without, Perry figures out a result fifty-six times as great as Kelvin's, while he regards it easily imaginable that 290 times as many years may have been necessary. Some excuse for supposing the inner materials of the globe to be the best conductors is found iu works of Dr. Robert Weber and Professor Joseph David Everett, well-known authorities on temperatures at various depths in the earth's crust. These experts are quoted by Perry to show that certain rocks greatly increase in conductivity with increase of temperature. This, with schists and micaceous gneiss, averages about 75 per cent for every 100 degrees centigrade; and at that rate Perry gets for an even earth perfectly solid at the start (to say nothing of a previous liquid or gaseous state), a result 1300 times as great as Kelvin.

At last accounts, the latter gentleman had agreed to look up Everett and Weber, and to consider the subject afresh.

ALVAN G. CLARK, speaking of "The Making of Large Lenses," makes special reference to one forty inches in diameter that he is finishing. The polishing is done by hand, and Mr. Clark is reported to have said that the heat of the "hand" so distorted the focus of the lens by expansion that it required three hours to cool it sufficiently for testing.

LORD RAYLEIGH and Prof. Ramsey claim to have discovered a new element in the atmosphere, an "inert gas," with its own boiling point, freezing point, critical temperature and critical pressure—all different from those of any other element. One of its properties is its invincible reluctance to combine with anything else. It will have nothing to do with oxygeu, chlorine, phosphorus, sodium, platinum or various other substances. Even the electric arc does not make it take companionship with anything. One important quality is a great puzzle. All the heat given to the new substance produces only the motiou of translation. In another respect argon presents difficulties. The great Russian chemist, Mendelejeff, has discovered an empirical law which associated the properties of the elements with their automatic weights. Now the new element has a density of thirty-nine or forty, which does not fit this law. "Argon," which is the name giveu the "new element," gives two spectra, the red and the blue, and it is this which raises doubt whether the investigators are dealing with one or two substanees. If the latter should prove true, then there is a new vista opened up, and it is suggested that perhaps one of the substanees will prove to be Professor Crooke's ideal protyle, the ultimate basis of matter from which all others are only combinations.

THE chemists of Americea, who have just held a general meeting in Boston, do not think chemical beefsteaks and other foods in sight for the human race just at prcsent, though chemistry has done much to develop the science of cookery, and given great variety to food and drink by the many essences of flowers and fruits that have been elaborated in the laboratory. The colleges of agriculture, and the agronomic experiment stations, of which there are now fifty-seven, have done so much to increase the productiveness of the the soil, and so reclaim unproductive lands, that Dr. Wiley, the retiring president of the Chemical Association, thinks that there is no economic reason for looking outside of scientific agriculture for the production of human food. On the other hand, Berthelot, an eminent European chemist, publicly proclaims his theory that artificial foods are in time to suppress those of nature; a time when the covering of the earth will be for beauty, as in a pleasure-park, and not "defaced by agriculture."

Mechanical Progress.

Tesla's Steam Engine.

Much has appeared in technical journals concerning this engine, and considerable speculation has been indulged in regarding its practicability. The engine is a vibratory direct-generating one, or steam dynamo. The scheme is to produce electric current without rotary movement, friction or moving joints even, except of a steam piston, which directly vibrates or reciprocates—an armature between magnets. Mr. Tesla gives out the following particulars of his direct steam engine:

"I had gone considerably into the study of the practical aspects of the work which I was to present, and my notion was that I was touching upon something which would lay the foundations of a novel industry, perhaps of more than one industry. I dwelt chiefly on those features which possessed a purely scientific interest, my desire being to present the subject very modestly, as I was not quite sure of some of the questions involved. A prominent engineer came to me and said: 'Mr. Tesla, I want to tell you something, but I fear I may offend you.' I knew what was coming, and so I asked what it was. He said: 'Well, don't you work on steam engines. You have done some work in electricity. If you stick to it you will do some good work, but if you work on steam engines you are bound to fail.' Another, to whom I showed the advantage of doing away with complicated mechanism, and generating electricity directly, said, after he had watched it for a long time, 'Couldn't you apply this to rotating motion?'

"One of the first impulses which guided me was to produce an absolutely constant motion, which would be independent of any friction losses, or gravity, or temperature changes within very minute limits. I wanted to produce a positive motion, so that I might operate what I called a disruptive discharge coil. With a device which I invented, I was able to maintain a vibration with perfect constancy. The device consisted of a spring which required several tons of force to spring a certain distance, and which was constantly kept in vibration by steam pressure or air pressure. In the beginning I used springs of tempered steel. These steel springs would break, though they had a section of two or three square inches. So I resorted to air springs. The air springs would not break, but they had no constant resistance. Then I made the chambers of the air springs communicate with the outer air. This device yields a constant vibration; and as the force which is driving it is many tons, and the friction but a very small matter, it is unaffected by the pressure, so I have a constant vibration. This is the device which I believe will be used for many purposes—for instance, for governing all sorts of mechanisms, engines and so on. It contains much of interest for scientific men, because with it I am now able to produce currents of perfectly constant frequency.

"When we look at a steam engine, and inquire where the power comes from that drives the steam engine, we will always find that the power comes from a little box, a cylinder with a piston in it, and all the other appurtenances are really but to keep it going. My first idea was to apply the motion of the piston, which is freely movable, to a magnetic field, to move a magnet or coil in a magnetic field, and so generate currents by this direct motion. We can reduce the weight of the engine for the same pressure and the same piston speed to $\frac{1}{30}$ or $\frac{1}{40}$ if not $\frac{1}{60}$ of its weight. We do away with all mechanical frictions.

"The engine designed according to my ideas has a mechanical efficiency of 99¾ per cent. In my construction the dynamo may consist of a simple coil of the maguet and a simpler coil, which is all immersed in the magnetic field. There is no useless wire, consequently dynamo and engine, if they are reduced considerably in weight, increase in efficiency. There is only one engine that can equal it in output, and that is the turbine. With the steam turbine we can obtain an enormous output, and that is the reason why the steam turbine, in my opinion, may be found a valuable adaptation for driving dynamos. In reciprocating mechanisms we can expand the steam at an enormous rate. It is perfectly practicable in these mechanisms, which I have been working up to obtain, if you want, a speed of 100 metres a second; and while I do not contemplate producing such speeds, yet it is quite possible to do it. As I am enabled now to work without a packing, the expansion occurs at an enormous rate; and the engine being of such character that the exhaust can be readily reduced to pretty nearly the atmospheric pressure and the mechanical friction is reduced to such a small figure that we can raise the temperature of the steam very considerably.

"I am now preparing a boiler which will give me up to 350 pounds pressure. If we want to drive motors we must have a long stroke and a slow frequency; if we want to light lamps then we want a very short stroke and a very rapid motion. It is very important in this mechanism, in which the power depends on the square, to obtain as high a pressure as possible. It is more economical to produce rapid vibrations than low vibrations. But, so far as the economy of the dynamo and of the engine is concerned, it is better to produce a long stroke, because a long stroke means a high velocity. I think I am not mistaken in believing that we are going very shortly to have a means at hand of producing twice as much electricity from coal as we can produce at the present time. This is subject, of course, to a test, but I am quite confident it can be done."

Discoursing on the weathering of fuels, Wm. White, Jr., gives information on the loss of value in fuel by exposure to the weather. Bituminous coals are stated to lose fifteen to twenty per cent of their volatile products during the first twenty days after mining. Exposed to a temperature of 284° they lose all their hydrocarbons. W. E. Koch gives the following illustration of the loss in value from storage: "About twenty years ago we had some labor troubles, and in anticipation of a strike our firm laid in a large quantity of coal, the bulk of it being under cover. The strike came on about a year afterward. An analysis showed that the coal when first put there contained about six per cent of ash and about thirty-one per cent of volatile matter. At the end of twelve months an analysis gave, ash sixteen per cent and about twenty-one per cent volatile matter. The coal being put under a producer to make gas put the producer out, and we had to shut down. I think that is the best instance I ever saw of weathered coal. Another case came under my observation. We had some coal sent over from the East Indies to England, it being shipped from Bombay. There were two lots, and both put on the ship at about the same time, one deep down and the other high up in the hold. The coal high up came through in good order. A chemical analysis showed this to have about thirty per cent volatile matter and the other twenty per cent. The one lot of coal made very good gas and good steel, while the other put the producer out. We had a similar experience with blast furnaces. We had an old bank of coke that had been lying undisturbed for a great many years. They said: 'This is all right.' So we put it into the furnaces, and it cost us about $6000 to get it out again."

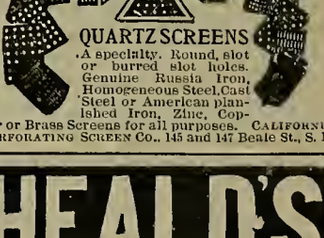
MacArthur-Forrest Process.
CAPITAL, - - - £110,000 STERLING.
To MINE OWNERS and others having Refractory Gold and Silver Ores hitherto untreatable at a profit, the MACARTHUR-FORREST (Patent) Process of Gold and Silver Extraction offers a solution of the difficulty.
Advisory Board in the United States: Thomas W. Goad, Manager; Hugh Butler, Attorney; John F. Bell; P. George Gow.
California and Nevada Agency and Experimental Plant, 23 Stevenson Street, San Francisco, Cal. P. G. Gow, Sole Agent.
Office: McPhee Building, Denver, Colorado.

—EASTERN PRICES BEATEN.—
SAN FRANCISCO Pioneer Screen Works!
JOHN W. QUICK, Prop.
Improved Facilities! Finest Work! Lowest Prices
Perforated Sheet Metals, Steel, Russia Iron, American Planish, Zinc, Copper and Brass Screens for All Uses.
—MINING SCREENS A SPECIALTY.—
221 and 223 First Street, San Francisco, Cal.



QUARTZ SCREENS
A specialty. Round, slot or barred slot holes. Genuine Russia Iron, Homogeneous Steel, Cast Steel or American planished Iron, Zinc, Copper or Brass Screens for all purposes. California Perforating Screen Co., 145 and 147 Beale St., S. F.

HEALD'S
Business College,
24 Post Street, - San Francisco.
FOR SEVENTY-FIVE DOLLARS
This College instructs in Shorthand, Type-Writing Bookkeeping, Telegraphy, Penmanship, Drawing, all the English branches, and everything pertaining to business, for full six months. We have sixteen teachers and give individual instruction to all our pupils.
A Department of Electrical Engineering
Has been established under a thoroughly qualified instructor. The course is thoroughly practical. Send for Circular. C. S. HALEY, Sec.

QUICKSILVER!

TUBBS CORDAGE CO.
(A CORPORATION.)
Constantly on hand a full assortment of Manila Rope, Sisal Rope, Duplex Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc. ☞Extra sizes and lengths made to order on short notice
611 and 613 FRONT ST., San Francisco, Cal.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

SUTTER CREEK DISTRICT.

THE MAHONEY.—*Record:* A pump has been put in the Mahoney mine which handles the surface water from the 200-foot level. This addition to the water-hoisting power is a great help, as the skips can now easily control the water below that point and steadily lower it in any weather. The shaft is drained to near the 550-foot level.

PLYMOUTH DISTRICT.

THE PHILADELPHIA.—*Ledger:* The Philadelphia is one of the properties being worked by the English syndicate. They have just installed ten stamps of their twenty-stamp mill, and started up. The rock they are putting through is taken from an open cut, making the cost of milling per ton very little. W. H. Kroning, under whose supervision the mining and milling is being done, estimates that when the twenty stamps are running, the cost per ton will not exceed fifty cents. By spring the mill will be supplied with concentrators and a blanket plant for saving sulphurets.

Calaveras.

SOLD HER MINE.—Mrs. J. J. McSorley has sold her mine in Chili Gulch to a capitalist, who proposes to develop it.

EMPIRE MILL.—Calaveras *Prospect:* The new mill on the Empire mine, adjoining the Pine Log, started up this week on first-class rock. The indications are good for a first-rate mine.

THE BOSTON MINE.—The old Esperanza, or Boston mine, of Buckeye Gulch, Mokelumne Hill, is being thoroughly prospected after lying idle for fourteen years.

THE BIRNEY MINE.—By a voluntary arrangement between the owners and the employes of the Birney mine the latter have taken charge of the mine until such time as sufficient gold is taken out to settle their several claims. The men agree incidentally to sink the shaft 100 feet, and do other necessary development work. Mr. Poor is the new superintendent of the property and James Denny foreman of the mine.

El Dorado.

SOLD FOR $6000.—*Democrat:* Joseph and Wm. Rupeley were in town Wednesday last, closing up the sale of the Lone Star mine. The mine is situated above Smith's Flat, and was sold by Marshall Hughes and Wm. Rupcley to a San Francisco company, the consideration being $6000.

Kern.

HAVILAH AND VICINITY.—Havilah, at one time the most flourishing mining camp in Kern county, lies six miles north of Keyesville and in the center of one of the principal gold-bearing regions. Most of the mines are located in the granite, just west of a belt of metamorphosed slate and limestone, which stretches for a considerable distance in a general northerly and southerly direction along the slopes of the mountains west of the town.

As late as 1887 a number of mines were worked regularly and in good ore, and several ten and twenty-stamp mills were running. After these were destroyed by fire on the 13th of November of that year, the people seemed to have become discouraged, and today most of the old mines, among them several that produced rich ore to the very last, are lying idle and have caved in. Among these are the Oriental, the Warrington, the Rochefort, St. Charles, Surprise, Eustacia, Confidence, Relief, Sovereign, New World aud Claybank. Work is done from time to time on some of the old claims and new prospects are opened up; but it requires capital and its judicious expenditure to reopen these mines and extract the gold which still remains in unquestionably large quantities. It is the unanimous opinion of men who have worked in these mines that the supply of pay ore is by no means exhausted. Mr. Charles E. Sherman, a gentleman who for years was superintendent of several of these properties, states that work on the Warrington mine was stopped in $16 ore, while the Rochefort averaged $40 a ton to the very last. The ore contained from one to two per cent of sulphurets which ran $400 a ton in the Rochefort and Warrington and $80 in the Clayhank.

The proper way to reopen these ore bodies would he by means of a drain tunnel, which would have to be about 1200 feet long, and to cost $5 a foot. Kern river, only five miles distant, might be harnessed and would furnish electromotive power for all necessary work.

On Bald Eagle mountain, northeast of Havilab, are several good prospects. There is also in this locality an antimouy mine—the Black Jack. Ore is shipped regularly from here to the reduction works in San Francisco, and brings $20 a ton on the dump.

Nevada.

THE DERBEC MINE.—*Herald:* The Derbec mine will resume operations in a few days. The mules, which are down on the ranch, have been sent for, and when they arrive the men will he put on again. The mine employed about thirty men when it closed down, several months ago. The cause of the shut-down was on account of the ditch being blocked with snow.

STAR OF THE WEST.—Mrs. Paul Richards has sold the Star of the West claim to W. W. Waggoner. It is a quartz ledge and lies just west of the Providence and the Home mines. The price paid is withheld.

THE NORAMBAGUA.—*Tidings:* Work has been going on at this mine for over a year upon a tunnel, now about 1100 feet long, to reach the former workings. The employes broke through lately into the old works between the fifth and sixth levels. This will lower the water in the mine, so that it will he practicable to at once begin operations upon a portion of the ledge which has never been worked out. Wm. Campbell, the owner of the Norambagua, will soon put a good force of men at work in the mine, and it will he made an ore producer. The mine adjoins the Perrin's and is located about five miles south of Grass Valley, near Forest Springs.

THE EAGLE BIRD.—The Eagle Bird mine started up last week. Twenty stamps are in operation.

WASHINGTON DISTRICT.

THE GIANT KING.—*Herald:* The Giant King mine, in the Washington district, upon which C. D. Lane had a bond for about six months, is to be worked by the owners hereafter.

Within the last six months the tunnel which taps the ledge has been driven ahead about 300 feet through very hard rock. It is now over 500 feet long and is in on the ledge, which is a mammoth one, about fifty-five feet, and the hanging wall has not yet been reached.

By the terms that have been made, Williamson & Cole, the owners of the mine, have full possession from this time on. They intend to run the tunnel ahead until they reach the hanging wall, when they will drift to the north, where they expect to encounter the pay shoot. This is believed to be the mother lode, which has paid well in various places where it has been worked. The ore is of a low grade, but it is in a condition to be worked economically. To the owners, or to anybody who will be satisfied with reasonable profits and is willing to figure closely, it is a valuable property.

Riverside.

NEW LIFE.—Till recently the mines in the western part of Riverside county have been worked on a par with the pick, shovel and pan plan of the average Mexican miner, operating in this State and Lower California, in which a living only was secured, and all that was wanted. But there is new life and blood in and about these miues, and many of the camps remind one of early California days, with the added improvement of machinery. Many of the best-paying mines have recently passed into the bands of Eastern capitalists, and the stamp mill is heard on every hand. As an example of the development and progress made, Good Hope bas grown from a miner's cabin or two to a nice little village, with a fine new schoolhouse, hoarding-houses, etc., in a few short months.

The great value of these mines is evidenced in the sale of the Good Hope mine recently, for $500,000. With the exception of a few days during the recent heavy rains, when coal could not he hauled, the twenty-stamp mill, put in by the new owners several months ago, bas been running day and night, with two shifts of thirty men each. But little is said by those managing this mine as to the amount of gold being taken out, they, perhaps, thinking this their own business. However, when it is considered that this mill, with a capacity of twenty tons per day, is running continually on $20 ore, and that the men have beeu paid regularly from $3 to $4 per day for months, is pretty fair proof that some gold is being taken out. The forty or more mines are now delving away at a depth of 500 feet, witb plenty of ore in sight.

The Alice, which lies thirteeu miles to the east of the Good Hope, has passed into the possession of a stock company, the principal members of which are J. M. S. Egan, until recently superintendent of the Good Hope; W. H. Griffith and M. Cantan, all recently of Colorado. A new five-stamp mill is being put in, with machinery of a capacity of teu stamps. The plant will be ready to commence pounding out the metal within two weeks. The shaft is only down eighty-five feet, but there is in sight enough $18 to $20 ore to keep the mill running for two years. There are on the dumps 500 tons of ore ready for the mill. The locators of this valuable mine were J. R. Cheatham, L. M. Wilson and L. Crain, the former still retaining an interest. Mr. Cheatham was formerly uight superintendant of the Good Hope.

The Rosalia, or more familiarly known as the Santa Rosa, one of the oldest mines of the group, has a ten-stamp mill in operation, running night and day, ou $15 ore. the ledge growing more valuable as greater depth is reached. This mine is largely owned by Massachusetts men. Messrs. Egan, Griffith and Cantan have interests, however. The output of this mine is bringing good money on the investment.

A new company has been formed to control the Santa Fe mine, and most of the stock having been sold, the mine has been lifted out of the financial embarrassments which have impeded its development heretofore. Work will be resumed on the mine in a few days, or just as soon as the details can be arranged. The grade of ore is on a par with that of neighboring mines. It is proposed to sink a shaft at the end of the big tunnel to a depth 500 feet below its present level.

The old Menifee mine continues to be operated day and night, and is making good money for its owners, with a five-stamp mill running on $10 to $12 ore. There is good profit in $8 ore.

The little Maggie has a ledge of only eighteen inches iu thickness, but the ore is of high grade, yielding $60 to the ton. The mine is being rapidly developed.

The Gold Prince, a mine but a few hundred yards from the Good Hope, and which has been lying idle for the past two years, for want of capital to develop it, is considered equally as valuable as its big neighbor.

Siskiyou.

GETTING READY.—A Henley correspondent of the Yreka *Journal* furnishes the following:

The fine weather of the last two weeks bas stimulated business. The gulch miners are bringing in small vials of gold dust. Ditch cleaners are at work, and prospectors are getting ready for an early start. Our depot is full of machinery, and it will not be long until we can hear the stamp of two mills at work on blue gravel, one at Jillson & Co.'s mine, the other at the Black Jack mine.

It looks now as though little will be done by the Porphyry Dyke men this season. They are still buying up property in that vicinity, and it is not likely they will do any work that will improve adjoining property, until they have secured all they want of it; then look out for the biggest plant in the county.

San Diego.

CARGO MUCHACHO.—Thomas Wiltyer has sold to Z. H. Lowman, for $3000, the Fair West, Eastern Exteusion, Homestake, American Girl and Black Quartz mines, in the Cargo Muchacho mining district.

NEVADA.

Lander Co.

THE CLIFTON TUNNEL.—The Austin *Reveille* is informed that the Clifton tunnel is now being run through ledge matter and everything looks favorable to the uncovering of a body of ore.

ARIZONA.

COPPER PROPERTY SOLD.—*Miner:* John W. Gerritt, the miuing man of Mineral Park, this week closed the deal for the Redenour copper property near the Grand Canyon of the Colorado. The price named is away up in the thousands. One-third of the purchase price has been paid down, and the balance will follow shortly. The purchasers are John R. White, of the Ninety-three Mining Company, Mineral Park, and the Graphic-Carbonate, Kelly, New Mexico; Howard R. Deacon, wholesale lumber merchant, Philadelphia, Pa.; Howard L. Haines, capitalist of Philadelphia, Pa.: Jo Davidson, wholesale jeweler of Philadelphia, Pa., and treasurer of the famous Utica mine of Colorado; Mr. Nealy, a wholesale lumberman of Philadelphia. The new company will begin work immediately. This sale was accomplished in less than a month from the time the parties first began negotiations.

TYSON MINERS HAPPY.—*Gazette:* Word comes from Tysou mining district that miners there are jubilant over the late rains. Dry washing has stopped in consequence, and prospectors are scattered between Harqua Hala and Ehrenburg. In the intervening valley, thirty miles by sixty, placering has gone on many years. Quartz mines yield gold in arrastras. G. W. Ingersoll of Colorado has a steam arrastra running. In Plomosa, east of Tyson, there is considerable activity; also in New Weber, south of there. The Gray cement-crushing mill is about to start near there, to treat the placer cement beds. John Agard and George Wilder are about to sell their mines at Chloride to Eastern parties. Every mine explored seems to justify a mill. Some 200 men are in the bills. Colorado parties will soon start a 40-stamp mill at Frost's claim near Tyson. Water has to be hauled to some of the camps and costs four cents per gallon. It is struck at a depth of twenty-eight feet in Tyson. Gaietta grass is in bloom and stock are doing well. Mountain sheep furnish fine meat. Tyson postoffice is fifty miles west of Harqua Hala, and twenty-two miles east of Ehrenburg.

NEED OF A MINING LAW.—Phœnix *Gazette:* The hill introduced by Mr. Marshall in relatiou to our mines and mining is one that should receive the approbation of the Legislature without delay. For years Arizona has needed a statute regulating and governing the location and holding of mining claims. Under our present practice a man or party of men can start out with a burro and a lead pencil, and by reason of their priority in a section containing evidence of mineral, locate aud hold a whole township of territory to the exclusion of others. It is a fact that in many of the mineral districts of Arizona a certain class of so-called mining men make it a business year after year to locate and relocate scores of mining claims upon which they are uuable and unwilling to perform one dollar's worth of development work. The United States law is evaded, and, as far as Arizona is concerned, is a dead letter with the average prospector. Now that our gold districts are attracting the attention of the investor, a law should be euacted protecting and encouraging the bona fide prospector, aud putting a quietus on the pencil artist of the mining regions.

COLORADO.

BIG MINING DEAL.—John F. Smith bas sold his one-fourth interest in the Moose mine at Cripple Creek to J. F. Maynard of Utica, N. Y. The amouut of stock held by Smith was 162,000 shares and the price paid was at the rate of 50 cents a share, or $81,000 cash. The experts who examined the property for Mr. Maynard placed the value of the mineral in sight at $256,000. Dividends to the amount of $84,000 have been declared in the past twelve months. This sale was the largest spot cash mining deal ever made in Cripple Creek.

AN ANNUAL STATEMENT.—The Colorado Central Consolidated Mining Company, in its aunual statement, says its debts amount to $125,000—$500 for labor, $100 for office expenses, $6000 for legal services, $116,500 contested judgment in favor of John Turck and other debts that will not amount to more than $2000.

IDAHO.

WARRENS PLACER DEAL.—Boise *Statesman:* George Riebold, from Warrens, says the sale of a tract of Warrens placer ground, owned by himself, ex-Governor Willey and others, has been consummated, the purchasers being Philadelphia capitalists. The tract embraces about 200 acres of ground, some of which has been worked and found to be very rich. The consideration, it is understood, was $26,000.

Mr. Riebold says oue man took forty-five ounces of gold from one of the claims included in the sale in eight hours. Chinese who own placers a short distance down the creek have taken out $2,500,000 in the past ten years. Mr. Riebold says it is a fact that two of the Chinese took out $1000 in one day.

The Philadelphians have purchased a dredging machine with which to work the ground. The machine is now at Pocatello. It will be shipped in as soon as spring opens.

The William B. Knott mine, recently sold by ex-Governor Willey to E. B. True for $10,000, is being worked with good results.

CAMAS NO. 2.—Hailey *Times:* Supt. Wood of the Camas No. 2 mine and mill came to town to-day, bringing a gold brick that weighed exactly 17½ pounds. At $16 per ounce Troy, the brick is worth about $4000. This was the result of fifteen days' run on fifteen stamps.

Another brick worth about $1500 having been brought in a couple of weeks ago, this makes about $5500 worth of bullion brought in. A cleanup is now going on at the mill, which will doubtless result in $1500 worth of gold additional.

In addition to the gold, sixty tons of concentrates have been shipped since the mill started up. These are worth $80 per ton, and amount to $4800. We thus have a total of about $12,000 for about twenty-five days' run of fifteen stamps. Mr. Wood says that during that time he ran 506 tons of ore through the mill. His expenses average $100 per day. He expects to do much better the current month than he did last, especially as he will run twenty stamps instead of fifteen.

YELLOW JACKET G. M. CO.—The Yellow Jacket Gold Mining Company, a Denver-New York combination, has its new twenty-stamp mill in operation and will add ten more stamps within sixty days. This mill was purchased last fall to replace the plant which was destroyed by fire.

MONTANA.

GENERAL MINING NOTES.—Butte *Inter Mountain:* W. E. Hall, formerly superintendent of the Alice, is engaged in putting the Poulin mine in good condition, and the rumor is again revived that the Poulin, Pacific and other properties in that locality are to be consolidated in one company, with Mr. Hall as superintendent. The people of Butte hope that the rumor is correct.

L. A. Dunham came in from Richmond Flat yesterday, bringing with him two bars of gold bullion—worth about $6500—from the Revenue mine. Mr. Dunham says that the prospects for the future of the Richmond Flat district are very bright, but all of the mining ground in the district is patented. No work had been done there for years until the Revenue people proved, by development, the value of that vein. The Revenue is now down to a depth of 300 feet, and with a milling capacity of from 40 to 45 tons a day will produce about $30,000 a month. The Revenue was recently sold to the present owners for $100,000 by the Turner Bros. and others. S. K. Knox, the owner of the Monitor, is sinking a vertical shaft on that property, and at the same time working in such a way as to make the ground pay all of the expenses. A recent shipment of ore from the Monitor assayed $156 to the ton. In the same shipment was a sample of 500 pounds that assayed $2000 to the ton. The owners of the Flat mine, in this district, are also preparing for active work in the future, as are the owners of various other properties in that locality.

NEW MEXICO.

HANOVER. — Silver City *Enterprise:* The new smelting plant of the New Mexico and Arizona Smelting Company was started on the first of this month. The smelter is handling 63 tons of ore per day on an average.

OREGON.

Josephine County.

A REPORTED STRIKE.—A strike in the old Dry Diggings mine, three miles east of Grants Pass, is reported. This is one of the oldest mines in southern Oregon, large amounts of gold having been taken out of it in early days, and it is still being mined every winter with good results. The main ledge has never been found, though it has been hunted for for many years. Two giants have been at work this winter on the property. Two years ago two young men found a pocket far up the hill, above any work which had ever been done on the property before, and took out sixteen ounces of gold from it. Taking up that clue, three miners began looking for the source of the lead this winter, with the result of finding a leader to what is supposed to be the main lead to the Dry Diggings mine. Some very rich quartz and dirt has been taken out, as high as $7 per pan being realized.

WASHINGTON.

GOLD CLAIMS IN DEMAND.—*Review:* A report is in circulation among mining men that the famous "Eureka" claim on Slate creek, in the Cascade range, bas been bonded to a coast syndicate for $100,000. The Eureka is the remarkable ledge of rotten quartz from which it is claimed $12,000 in golden nuggets was taken by its discoverers last fall before the snow came. If it is anything more than a big pocket the general idea is that $100,000 is a beggarly sum to offer for it.

While Slate creek is certain to be dammed by the stampede of gold-seekers iu the spring, it will not be the only part of the Cascades that will be explored pretty thoroughly this year. All along the Methow valley there will be dozens of them. Some are going farther up the country, near the boundary line, where few white men bave ever left their footprints. It is claimed that one man, who was iu there last autumn, took out $14,000 in a single month from a rotten quartz ledge.

Letters received from Everett, Tacoma and Seattle say that many of the mining men on the Sound are getting the Alaska craze. Spokane prospectors do not seem to be tempted in that way. So far as is known, none of them have yet decided to go. They say it is too expensive a trip and too hard a country to work. As a business proposition they prefer hunting gold in central Idaho, the Okanogan country or the Cascades.

Coast Industrial Notes.

—The Fair executers will proscoute the work of reclumation of the Nerth Beach property.

—The *Railway Age* says that the story that Debs is going to San Francisco is "pure humbug."

—New Westminster is manufacturing pipes for the Cariboo and Horsefly companies' hydraulics.

—The coast steamship war makes $4 the present possible passage price from this city to Seattle.

—The Chinese Six Companies are getting Chinese on the coast to draw their money and ship it to China.

—The electrical workers of San Francisco organized under the auspices of the Labor Council last week.

—A tri-weekly line of steamers between Oakland and the Sacramento and San Joaquin river ports is projected.

—The Southern Pacific Company has contracted for 700 ventilated fruit cars for use next season. They will not require the use of ice.

—The Currie Iron Works at New Westminster were sold for $5000, and the book debts for nine cents on the dollar. The works were assessed for $19,000.

—Redo & Co. are reported about to put on a line of freight steamers between Mexican and South American ports in opposition to the Pacific Mail Steamship Co.

—D. B. Hanson, Pacific coast representative of the Edward P. Allis Co., Milwaukee, has secured letters patent on an offsetting sawmill carriage—a clever device.

—The *Republican* hears that the employes of the Truckee Lumber Company are to have their wages reduced twenty per cent. The report is denied by the company.

—Grain freights out of San Francisco are quoted at 21 shillings. There are now 83,767 tons of discaraged bottoms in port, as against 43,933 tons at the same time last year.

—The Northern Pacific receiver's report for November shows balance for October, $1,378,917; receipts, $3,896,338; disbursements, $2,100,577; balance to December, $1,735,760.

—F. G. Curtwright is overseeing the installation of a 2500 H. P. transmission electric plant at Bakersfield, power being secured from the Kern river, twelve miles distant.

—Active arrangements are in progress for a steamship line between Portland and the Orient, to be operated in connection with the O. R. and N. Company and the Great Northern railroad.

—The Pacific Storage Battery Company has been incorporated in this city; directors—Thomas Addison, Robert B. Elder, Fred F. Barhour, F. M. Ray and Samuel E. Kearney. Capital stock, $20,000, all subscribed.

—The ice crop in the Truckee river, representing a present invested capital of $600,000, is now being "harvested." It is Truckee's only water industry and gives employment to a large number of men.

—The Monarch Consolidated Gold Mining Company has filed articles of incorporation in Oakland. Capital stock, $500,000, with P. C. Gayetty, J. W. Woodward, F. C. Watson, A. M. Benham and W. R. Thomas of Oakland as directors.

—The new J. J. Cousin's drydock was successfully launched at the foot of Devisadero street, this city, last week. It is 180 feet in length, 61 feet wide and 27 feet high, contains 24 watertight compartments and is of unusual lifting power. It is a California construction throughout.

—On the Mexican international railway construction has commenced on the branch from Monclova west to the mining town of Sierra Mojada, about 160 miles. The line was partially graded in 1892. Work has also been commenced on the branch from Riata southeast to Monterey, 60 miles.

—Three forty-foot guns are en route for Fort Point and Lime Point. They weigh fifty-seven tons each, have a diameter of 46 inches, and a circumference of 12 ft. 2 in. at the greatest point. They are expected to furnish adequate defense against any marine foe that would elude the new mortar batteries.

—The total expenditure of the Escondido irrigation system to date has been $136,408.10. The cash receipts from the sale of bonds have been $151,070, leaving a balance of $14,661.90 on hand. There is $76,440 due on bonds, and this, with the amount on hand, leaves $91,101.90 as the sum available for completion of the system.

—The Santa Clara Valley Railroad Company has incorporated with a capital stock of $300,000. Directors—F. Smith, president; L. A. Sage, P. R. Sterne, W. O. Watson and W. P. Hentry. The company proposes to build sixteen miles of standard gauge road from San Jose to Saratoga and to Santa Leland.

—There are sixty-six hot springs in Nevada and a belt of hot water underneath the State, which, if tapped by artesian wells, would prove of great commercial benefit to the State. Past legislatures have attempted to foster the enterprise by paying bounties to successful artesian well sinking, but they were too small to be of any practical good.

—By a vote of 36 to 25 the United States Senate voted last Saturday to inaugurate the project of laying a cable from the Pacific coast to Hawaii. An amendment to the Diplomatic and Consular Appropriation bill was made, giving $500,000 for beginning work on the cable and authorizing the President to contract for the entire work, estimated to cost $3,000,000.

—The Californian Water Works and Irrigation Co., Ltd., is an English corporation operating in Layo Co. About eight miles of canal are now under active construction, of which several miles are completed. The total length of canal will be eighty-three miles, and it is estimated that it will irrigate 332,000 acres of land. It is expected that eighteen miles of the canal will be finished by next spring.

—The scheme to tap and partially drain Goose lake, which is situated in this State and in Oregon has several times been agitated and met by strong opposition. Now it comes up in the shape of a bill introduced by Congressman Geary, granting the right of way to construct a canal from the lower end of the lake, in a southeasterly and southwesterly direction to Upper Pitt river, for irrigation and other purposes.

—Jas. S. Brownell, Western agent Pruc Vanning Machine Company, 132 Market St., San Francisco, reports the following sales: Osborn Hill mine, Grass Valley, Cal., three 4-foot patent lip belt vanners; Virginia City, three 4-foot plain belt machines; Eureka & Excelsior mine, Sumpter, Baker Co., Or., one patent lip belt vanner; Muzatlan, Mexico, eight 4-foot plain belt vanners; Australia, three 4-foot plain belt vanners.

—The extension of electric railways in the past year in San Francisco is noticeable. On Mission and Kearny streets, two prominent thoroughfares, electric cars have been recently placed, and in the western part of the city two more lines are in process of construction. This week a fifth new electrical railway project will be begun, to be completed next July. This road will be over four miles in length, beginning at Bay St. and extending through the southwestern part of the city.

—The Colorado River Irrigation Co. has a mammoth scheme to reclaim an arid region of 1,000,000 acres in southern California and 500,000 acres in Baja California, reaching from Indio, San Bernardino Co., to the Gulf. It is proposed to begin work on the main canal next week. It will be 250 miles long, and for the first twelve miles will be 156 feet wide, carrying ten feet of water. The initial point is "Pot Holes," about ten miles from Yuma. The water to be used is from the Colorado river.

—During the season of '94 the Cutting Fruit Packing Co. of Colton, Cal., bought of the fruit growers 2,955,553 pounds of green fruit, for which they paid out $25,116.74, or an average of nearly $20 per ton. For labor in handling this fruit they paid out $19,335.20, most of which was kept right at home and was distributed where it would do the most good. The company packed for the season 1,083,000 cans of fruit and their shipments for the season up to date are 181 carloads of dried and canned fruits.

—The Renton, Wash., coal mines are to be reorganized on the co-operative plan. The capital stock of the company is to be $100,000, divided into 1000 shares of $100 each, payable in monthly installments of $10, or in full, whichever the subscriber prefers. One of the prime features of the enterprise is right of employment to shareholders, limitation of number of shares, steady employment to those who perform their duty faithfully. In addition, the company will aim to have eight hours constitute a day's work and pay a full day's wages.

—Articles of incorporation of the San Francisco and San Joaquin Railroad have been prepared by the secretary of the committee of promoters of the road. The capital stock is placed at $6,000,000, divided into 60,000 shares of the par value of $100 each. The length of the road is estimated at 350 miles, and it is set forth that $350,000 have been subscribed, to meet the legal requirement of $1000 per mile subscribed, of which ten per cent has been actually paid in. The total amount of subscriptions has reached $2,200,000.

—The Spokane *Chronicle* says that the country extending from Spokane to the Sound has been hard hit by the dull times. At Spokane former millionaires are penniless, with nothing to do. It is said of one man, who owned a brick block, that he is now glad to get the janitorship of the building he formerly owned. Another man, who had a salary of $500 per month and owned a vast deal of property, is without a cent and keeps himself employed by keeping books, without pay. One informant said that one man was especially happy because he owed only $5000.

—The record of the steamer Flyer, plying between Tacoma and Seattle, for the year 1894, is probably without a parallel in the United States. Her running time, from wharf to wharf, is one hour and twenty-five minutes, and she makes four round trips a day, six days in the week. During the past year she made 1249 round trips, covering a distance of 68,695 miles. Not a single trip was lost, not an accident of any kind occurred, and the total time lost during the year was forty-three minutes, showing that her arrivals and departures were like clockwork.

—The Edward P. Allis Co. branch office, 31 Main St., this city, have received an order for a cross-compound condensing engine of the Girder frame horizontal type, with Reynolds-Corliss valve gear. Cylinders are to be 14 and 26 inches in diameter by 36-inch stroke; drive wheel, 16 feet diameter by 30-inch face; weight, 14,500 lbs. They are putting in a 36"x120" water jacketed furnace for the Standard Smelting and Refining Company, of Durango, Colo., and two 36"x120" water jacketed copper furnaces, with complete Reynolds-Corliss engine outfit for the Detroit Copper Mining Co., at Morenci, Arizona.

—Judgments in the Superior Court in Seattle, Wash., are still piling up against D. T. Denny and his sons. Recently defaults were signed in two actions by the Northwest General Electric Company and one by W. J. Grambs on assigned promissory notes aggregating $34,791, and a confession was made in a suit on a $9000 promissory note executed to George F. Gund. The notes held by the electric company are dated March 1, 1893, and are as follows: Northwest General Electric Company, $24,000; L. H. Griffith ($20,000, $12,000, $10,000, $8,750, $5,250), $56,000; F. T. Blanck, $4,134.75; Jacob Furth, $656.25; total, $84,791. The amount with interest and attorneys' fees is now in the three former cases $97,298.52, and in the Gund case $9,455.62, bringing the grand total to $106,753.12. This sum, together with the confession in the cases of the Puget Sound National Bank and F. T. Blanck, makes a total of $409,372.58.

—The following, furnished by the secretary of the Tacoma, Wash., Chamber of Commerce, is a statement of the Tacoma smelter for the month of January, 1895: Number of men employed, 76; pay roll, $5556.16; wood choppers and teams, $304; total, $5860.16. Product—4000 bars bullion weighing 412,884 pounds; copper matte weighing 182,900 pounds. Contents: 2,059.40 ounces gold at $20.67 = $42,567.80; 46,238.62 ounces silver at 60 cents = $27,743.17; 448,167 pounds lead at $3.022 per cwt.=$13,557.05; 72,174 pounds copper at 9½ cents per pound=$6,856.53. Total, $90,724.55.

—The two largest locomotives in America go into the service of the Southern Pacific Co. on the Mountain division next week. The weight of each engine without the tender is 169,000 pounds; the total weight, ready for service, is 250,000 pounds. The driving wheels, of which there are four pairs, are fifty-one inches in diameter. The boilers are seventy-two inches in diameter, the steam cylinders twenty-two inches, with a twenty-six-inch stroke. The locomotives exceed in size and strength the "decapods" used on the "switchback" division of the N. P. R. R. some years ago, and will be used in the Tehachapi and Sierra Nevadas.

RUPTURE!

It has been considered by the medical profession that hernia—commonly called rupture—was incurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But DR. J. C. ANTHONY, of 86 and 87 CHRONICLE BUILDING, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patient no pain, and those living near enough do not lose any time only while in his office once or twice weekly. He guarantees every case he treats, and does not ask a man for a dollar unless he cures him, so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medical College, of New York City.

OUR PIPE IS FOR SALE.

For Hydraulic Mining and Irrigation Purposes Our Sheet Iron and Sheet Steel Riveted Water Pipe Is Unexcelled.

We Have Also a Large Line of the MATHESON JOINT (Lap-Welded) Pipe, for Which We Are Agents.

Our Prices Are Low; Our Pipe Is Superior, and We Want More Business. May We Quote You Prices?

PIPE FITTINGS, TOO.

RISDON IRON WORKS,

Electrical Progress.

Electricity from Sunlight.

That which persuades the compass to point northward and a "dipping needle" to incline its northern end downward is the magnetism resident in the earth itself; and this is probably permanent. There are, however, certain deflecting forces which operate either regularly or irregularly to cause both of these instruments to vary in their indications. There is similar interference with other magnets, arranged to test the strength rather than the polarity of the earth's magnetism. Some of these disturbances, Professor Bigelow thinks, are due to an influence proceeding along curved lines from the polar regions of the sun, and impinging on our globe at right angles to the plane of the earth's orbit. But it has been strongly suspected by various authorities that certain other effects, such as the diurnal oscillation of the needles, are produced by a thermal or electric influence, following a straight line from the sun to the earth, and hence parallel with the solar light rays. That the eastward swing of the compass every morning should begin at an earlier hour in summer than in winter, and that the range from the most easterly position to the most westerly (which latter is usually attained between noon and 2 P. M.) should, in our hemisphere, be more ample when the sun is north of the equator than when it is south, has lent strength to that suspicion. The notion that this oscillation was caused by electricity excited in our atmosphere by "convection currents"—that is, air set in motion by the sun's heat—has been widely entertained, and still has its advocates; but since Hertz confirmed Maxwell's electro-magnetic theory of light there has been a growing disposition to think that the diurnal swing of a declination needle resulted from a direct electric radiance, nearly or quite identical with the luminous radiance.

The instrument known as an actinometer formerly employed only chemical means for detecting the intensity of the sun's rays, and only chemical or actinic effects were thus measured. But a long series of experiments in this particular field has led Messrs. Rigollot and Marechal to invent an actinometer in which a perceptible electric current is set flowing by solar action through a copper strip from the end of the instrument which is exposed to strong sunlight toward the other, which is shielded from light. This instrument has been developed sufficiently to transmit signals over a wire for more than six miles. When luminous rays were focussed on the sensitive plate of the apparatus at one point, a galvanometer in the circuit at another point was instantly deflected; and as soon as the light was turned off, the needle returned to its normal position. If the air, or the earth, is similarly influenced, then, it is argued by M. Marechal, there should be a system of electric currents always flowing from the darker regions of the earth's surface toward that area which is most brilliantly illuminated; an area which is continually shifting through the earth's axial rotations. Whether the observed facts fit this theory closely is perhaps open to question. But the phenomena here described are highly interesting in themselves, even if they do not directly explain the diurnal swing of the magnets. Indeed, they may have a more practical value, either in establishing a new system of telegraphy or the storage of free energy for commercial purposes, or both. There is a strong appeal to inventive genius here.

MASCART found that an electric glow lamp of thirty-two candles set fire to cotton wool saturated with India rubber, and packed around it, in two minutes, to black silk in six minutes, and to a double layer of cotton cloth in two minutes, says the *Gas World*. The same materials not saturated with India rubber did not take fire. Capt. Exler of the Austrian army now finds that a sixteen-candle lamp, sunk in paraffine, reaches a maximum temperature of 94° C.; one of twenty-five candles 101° C. A layer of gunpowder, ecrasite or pulverulent pyroxyline is not set on fire by this; the ecrasite melted and the gunpowder lost all of its sulphur. If the material be spread on a substance—for instance, wood—which is opaque to heat rays, the action is more marked when the lamp is brought very near to it; the ecrasite melts, the pyroxyline darkens, the gunpowder loses its sulphur, and the niter melts and the wood chars. Two lamps in a cavity of wood get up a temperature of 215° C., but the explosives did not go off, though they decomposed. When the cavity was filled with water it boiled in fifteen minutes. The spark produced on turning off the flame only kindles these explosives when they have become very dry, but the spark produced on switching off a feeble resistance between two lamp wires can do so readily. If the lamp breaks, pyroxyline or gunpowder does not ignite, but an explosive gaseous mixture will; whence, in dangerous surroundings, the lamp wall should be thick, and the lamp should never be brought too near combustible material.

Erratic Electric Engine Governing.

The *Electrical Engineer* notes that the time and ingenuity which have been expended in the designing of governors for regulating the speed of electric lighting engines have resulted in a number of very sensitive types. But if all the care bestowed on them is to be nullified by extraneous conditions not contemplated in their design, much of their value will be lost. A case of this nature was recently brought to our attention, which, we think, merits further inquiry, and which we deem of interest to all those operating direct connected engines.

The engine and the dynamo in question are directly connected, and when the plant was installed and started the engine performed in a satisfactory manner both to the purchaser and to the maker's representative. After a time complaints were received because of unsatisfactory regulation. From the character of these complaints it was concluded that there might be some defect in the governor, and the manufacturer incurred the expense of sending a complete new governor, requesting that the old one be returned. The new governor was placed, adjusted and the plant started, and the report came back that the regulation was perfect. In the course of a week or ten days complaints were again entered on the score of unsatisfactory regulation of the governor. The thought then occurred to the engine builders that possibly the governor was affected by magnetism. They conferred with the makers of the dynamo and were told that in their judgment such could not possibly be the case.

It has since been learned that a monkey wrench will be held fast to the rim of the governor wheel when the engine is under full speed. The speed of the periphery of this wheel is about 5400 feet per minute. When the engine is in service the force is sufficiently strong to pull a man, standing at the front or crank end with a wrench held out within two feet, into the engine. Any magnetic substance, such as iron or steel, if placed on the throttle or valve wheel, is held firmly. The distance between the center of the dynamo and the eccentric is about forty-eight inches.

The question therefore arises whether the governor can be affected by the stray magnetism of the dynamo, and whether such a condition in a plant as indicated above may not materially effect the cost of light.

PATENT SOLICITORS.
ESTABLISHED 1863

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S.F.

The Mineral Hydrocarbons.

Their History, Geography, Geology, Physical and Chemical Properties and Uses.

NUMBER XXII.

Written for the MINING AND SCIENTIFIC PRESS and copyrighted 1894, by Henry G. Hanks, F. G. S.

1890.—The total capital invested in the petroleum business in California was $2,186,958. Total number of producing wells, 89. Illuminating oil sold for $2.55 and fuel oil for $1.43 per barrel.

A new oil field was developed in Los Angeles county, two and a half miles southeast of Newhall. The new district was named "Ellesmere," referred to in the following newspaper clipping:

"The Newhall oil district is situated thirty miles west of Los Angeles, on the main line of the Southern Pacific Railroad. The main oil belt extends for about eight miles through the San Fernando mountains, in a southeasterly and northwesterly direction, the formation being entirely of sandstones and oil-bearing shales. Developments have recently been commenced on the east side of Newhall in what is known as the Ellesmere district. The remarkable depth of the oil-producing sand has not been excelled anywhere, ranging in thickness from 350 to 785 feet. The first wells bored, fifteen years ago, still yield large quantities of oil, with no signs of failing. At Pico canyon there is a strip of land 840 feet wide and 3800 feet long which has yielded more than one million and a half barrels of oil and still produces, without any appearance of giving out. There are now fifty wells in this section with a daily aggregate production of 900 barrels, which amounts is steadily increasing."

The year's yield of California petroleum was 307,360 barrels, and the total State production was 3,590,622 barrels.

1891.—There was an oil excitement this year in Humboldt county at the old Petrolia and Mattole districts. On the 13th of April a company was organized with a capital of $200,000. A well was soon commenced, but at last accounts no material success had been met with.

The State yield for the year was 474,500 barrels, and the grand total since the commencement in 1869 was 4,065,122 barrels.

While this is but a small yield as compared with that of Pennsylvania and New York, still it is very important to our State, so deficient in fuel.

In April, 1894, the British tank steamer Bawnmore arrived in San Francisco with her first cargo of crude Peruvian mineral oil, amounting to 20,000 barrels.

A full shipload would seem to be a very considerable quantity, but to equal the output of California for sixteen years she would have to make 203 full voyages, and there would still be a deficiency of 5126 barrels. To accomplish this she must make nearly thirteen full voyages a year, which is an impossibility; that is to say, if she had been employed during sixteen years to her full capacity in conveying California petroleum to Peru, she would have fallen far short of the task.

These calculations will convey a good idea of the magnitude and importance of the petroleum production of California. What it may become in the future, who shall predict?

The estimated State production of asphaltum was 50,000 tons, and the capital invested in mining, transportation and application was $2,500,000.

1892.—A special train of eleven cars loaded with 150 tons of refined Buena Vista asphalt, refined at Asphalto, was sent to Sedalia, Missouri, where it was used for pavements. Shipments were made during the same year to Portland, Denver, Ogden, Kansas City, Los Angeles and elsewhere.

1893.—Of the numerous State localities only five counties were producing asphaltum, as follows: Kern, San Luis Obispo, Santa Barbara, Santa Cruz and Ventura.

GREAT BRITAIN'S net imports of gold amounted to $59,586,875 in 1894, as compared to $26,662,270 in 1893. That's where a lot of our gold has gone.

Alaska Mexican Gold M'g. Co.

Douglas Island, Alaska, July 31st. 1894.

William J. Chalmers Esqr.
Pres. Fraser & Chalmers.
Chicago. Ill.

Dear Sir:-

Your letter of July 7th. is duly received.

In regard to your enquiry regarding our Riedler Compressor, supplied by your Coy, over eight months ago, I must say, that the Compressor is giving excellent results, and every satisfaction, while running either by steam, or water power.

During the last twelve years, I have seen operated, and have operated, many different makes of air Compressors, including the Eclipse, Reliance, Burleigh, National, Rix, & Firth, Ingersoll Sargent, etc. etc. and in no instance, have any of the above given the results of the Riedler. Therefore, I have no hesitation in saying that the Riedler, is the best, and most economical Compressor on the market today. We have made comparitive tests here, of the Ingersol Sargent, and Riedler, which show, greatly in favour of the Riedler.

Yours very truly,

R. Ld Duncan Jr

SECRETARY HERBERT will ask Congress for authority to transfer to the Interior Department all the wooded lands not needed for naval purposes. Live oak timber was once the chief material employed for our warships, and to insure a supply of it the government set apart large tracts covered with trees in some of the Southern States. In these days of steel hulls the need of this provision has ceased, and, in fact, there are now lying at the various navy yards thousands of feet of seasoned live oak that can neither be used or sold. Naturally, the Navy Department long ago ceased to concern itself with watching its live oak tracts, and there is no evidence to show that trespassers and squatters take advantage of this fact, while in some cases the reservations may obstruct settlement.

THE public revenues of a State cannot be better employed than in the exploration of her mineral resources by the best equipped geologists and mineralogists that can be secured for the service. And, in addition, an appropriation should be made to build up a State mineralogical, geological and archæological museum, while yet there is material.—Black Hills Mining Review.

Market Reports.

The Markets.

SAN FRANCISCO, Feb. 14, 1895.

A little weakening in lead and copper and a hovering of silver around the 59¾ mark characterize the week in those metals. There is a heavy movement from all quarters of gold to New York. Over $5,000,000 left London for New York this week and about half that amount has been called for from this city, the local supply being principally shipments direct from the Sub-treasury. Gold is coming into the United States mint here at the rate of $50,000 daily. The present movement is responsive to the proposed placing of a new issue of $65,000,000 government bonds.

Mining Share Market.

SAN FRANCISCO, Feb. 14, 1895.

Comstocks were firmer during the week; the amount of business was limited. The Holmes Mining Co. is about to sell the tailings at its Belleville mills, and the quantity of low-grade ores accumulated. Supt. Leggett of Bodie will attend the meeting of the Standard Cou. next Monday. The Standard people are preparing to put in a new generator, which will run the pumps and hoist, the power being carried through the tunnel. The pump at the cyanide plant will also be worked by electricity and an electric motor will raise the cars loaded with tailiugs to their present level, by means of a cable and temporary tracks, after which they will he pushed into place by the men, as they were last summer.

The sixty-four men working at tbe Crown Point will have an enforced vacation the rest of the month, waiting for repairs to the hoisting machinery, which was badly smashed last Monday. Bullion valued at $20,000 has been received from that mine on January account.

The *Enterprise* reports a strike of some importance in the Chollar mine. The new ore body is about 40 feet below the 550 level. The last official letter from the Chollar said "the winze below the 550 level is down 37 feet. The east side is in quartz of fair assays, value samples running from $20 to $30 per ton."

Since that publication the vein of quartz was working toward the east. A drift was started and extended fifteen feet. The face of the drift is in ten feet of ore, which, it is thought, will average between $30 and $40 per ton at the battery.

The vein contains some rich places, although it is not pockety in its nature. It is thought that there are no old workings in the neighborhood to interfere with the vein now being followed. The find is within twenty-eight feet of the Hale & Norcross line.

The hullion statement of the Chollar for the month of January is as follows: Worked at the Nevada mill 960 tons of ore. Gross proceeds in hullion, $23,580.53. Cost of reducing, $5760. Net proceeds in hullion, $17,820.53. Assay value per ton, $33.49. Gross average per ton, $24.56. Net average per ton, $18.56. Mill worked up to 73.3 per cent.

In the Savage, on the 950 level, the last crosscut from the fourth floor of the north upraise is advanced thirty-seven feet; face in quartz assaying $7 per ton. On the 1100 level, in the north drift from the east drift, they continue to extract fair-grade ore from the sill floor up to the tenth floor.

On the 1050 level in the south drift from the east drift they are extracting ore of good quality and the grade of the ore has improved in stoping upward from this level. In drifting south from the east crosscut they are also finding streaks of good ore. From the face of the south drift on this level they have advanced a crosscut west fifteen feet, and the last three feet are in ore of good quality. During the week they have hoisted 120 cars of ore. Car samples average $35 per ton.

The following illustrates the changes of the week:

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING FEBRUARY 5, 1895.

533,521.—PETROLEUM FURNACE—Wm. Bootb, S. F.
533,788.—RULER—A. S. Cooper, Santa Barbara, Cal.
533,792.—BUTTON-HOLE GUIDE—C. Donovan, S. F.
533,587.—PRESERVING TIMBER—J. S. George, Newport, Ogn.
533,642.—CAN OPENER—J. Gould Jr., S. F.
533,803.—BOILER FEEDER—M. Gregson, Philomath, Ogn.
533,534.—SAWMILL SET WORKS—D. B. Hanson, S. F.
533,645.—CARAMEL BOX—W. E. Henry, S. F.
533,646.—ROTARY ENGINE—R. Hewson, S. F.
533,466.—CUTTER GUIDE—Howard & Scoggan, Oregon City, Ogn.
533,716.—FRUIT GRADER—Luce & Barngrover, Los Gatos, Cal.
533,823.—BOOTJACK—J. I. E. Nelson, Cedar Home, Wash.
533,666.—PAINT REMOVER—Pfaffle & North, S. F.
533,739.—DRENCER SPUD GEAR — W. B. Pless, Stockton, Cal.
533,740.—DRENCER—W. B. Pless, Stockton, Cal
533,741.—DRENCER HOSE GUARD—W. B. Pless, Stockton, Cal.
533,667.—FIRE ESCAPE—H. F. & L. Pokorny, Seattle, Wash.
533,669.—HOISTING APPARATUS—L. Rosenfeld, S. F.
533,610.—ELECTRIC RAILWAY—A. Rosenholz, S. F.
533,687.—BARREL SUPPORT—R. Walker, Oakland, Cal.
533,768.—HORSE POWER—E. J. Wood, Beckwith, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

CARAMEL BOX PARTITION AND MACHINE.—William E. Henry, San Francisco, Cal. No. 533,645. Dated Feb. 5, 1895. The object of this invention is to provide a movable partition which is especially adapted to be employed in boxes in which caramels are sold and shipped. These boxes are made of pastehoard, or other suitable material, and each individual rectangular caramel is wrapped in a thin waxed paper to prevent their sticking to the sides of the box. In my invention, partitions are made for these boxes consisting of single strips of metal formed into longitudinal strips with integral transversely projecting arms upon opposite sides. To make these strips I employ a machine, cousisting of blocks separated from each other to form a narrow channel for the reception of a strip of metal and levers fulcrumed at opposite sides with bars connected therewith adapted to slide in slots or guides at right angles to the strip of metal, so that hy moving the levers the strips are folded into the shape desired to form the partitions.

ADJUSTABLE BARREL SUPPORT. — Robert Walker, Oakland, Cal., assignor of one-half to Jacob Kornahrens. No. 533,687. Dated Feb. 5, 1895. The object of this invention is to provide a support for barrels from which the contents are heing drawn whereby the harrel is gradually tilted as the contents are reduced, and brought into position to discharge the whole of the contents without agitating or shaking. It consists of a stationary support having segmental depressions upon opposite sides to receive and support the keg or harrel, and a spring-actuated arm having one fixed end, and the other end inclined upwardly with a segment fixed to it and adapted to fit the end of the keg or barrel, together with a rod or har with notches so that the spring may he drawn down hy means of this bar and the notches engage a suitable catch to hold it down until the harrel is in place. After this the notched har is released, and the spring acting against the upper end of the harrel, will gradually raise it as the contents decrease, so that the liquid can he drawn from the spigot at the other end.

ROTARY ENGINE. — Robert Hewson, San Francisco, Cal. No. 533,646. Dated Feb. 5, 1895. This invention consists of a wheel with a series of concentric annular chambers or huckets into which the propelling medium is admitted under pressure and couducted successively from one series of chambers to the next, operating expansively from each chamher to the following one. The wheel is mounted upon a shaft and adapted to rotate within a closed casing. It has two or more series of concentrically arranged huckets, open at one side only. This side moves in contact with a flat disk or diaphragm, which forms a constant wall for the open side of the huckets. A steam chamher is located upon the opposite side of the diaphragm in line with the outer row of buckets, and passages are made through which steam is delivered against the front wall of the huckets, to impel the wheel. Slotted openings are made diagonally through the disk or diaphragm opening from the steam chambers into the chamher where the wheel rotates. The arraugement of these passages is such that the steam is exhausted from each exterior hucket into the next interior steam chamber, and thence into the adjacent series of huckets, so as to act expansively in each case, the steam heing finally allowed to escape through an exhaust passage.

CAN OPENER.—James Gould Jr., San Francisco. No. 533,642. Dated Feb. 5, 1895. This invention relates to a device for opening cans. It consists of a shank having an attachment for the application of power, a flattened hook at the opposite end, formed with a sharpened convex outer curvature, a sharpened concaved curvature on the inner side, and an expanded or thickened point which is adapted to engage the inner wall of the can to serve as a stop and prevent the hook from heing drawn out while cutting. The convex outer edge or point is first forced through the metal so as to hring the hook portion inside; then, by pulling upon the hook, the inner edge cuts the tin in the line in which it is drawn until the can is properly opened.

Bucyrus Steam Shovel and Dredge Co.

SOUTH MILWAUKEE, WIS., Jan. 28, 1895.

To Whom It May Concern:—The undersigned have to-day heen appointed receivers of the Bucyrus Steam Shovel and Dredge Co., and, as such, have taken possession of all property, assets and husiness of the company. You are hereby notified that all payments should be made to us.

Under the orders of the court, *the business of the company will be prosecuted as usual.* Existing contracts will he executed, unless notice to the contrary shall he given, and orders for new machinery, repairs, supplies, etc., will he received on behalf of the receivers and promptly attended to.

All supplies and material which may come in subsequent to this date will he for account of the receivers. Soliciting your continued patronage, we are very respectfully yours,

JOHN S. GEORGE,
HOWARD P. ELLS,
Receivers.

The ahove is self-explanatory. The business continues without interruption, there being no check nor delay in the filling of orders, etc.

Assessment Notices.

GOULD & CURRY SILVER MINING COMPANY—Location of principal place of business, San Francisco, Cal.; location of works, Virginia, Storey county, Nev.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 17th day of January, 1895, an assessment (No. 75) of fifteen cents (15c) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, room 69, Nevada block, 309 Montgomery street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 19th day of February, 1895, will he delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on TUESDAY, the 12th day of March, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

ALFRED K. DURBROW, Secretary.

Office—Room 69, Nevada block, 309 Montgomery street, San Francisco, Cal.

BULLION MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Virginia district, Storey county, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 21st day of January, 1895, an assessment, (No. 44) of 10 cents per share was said on THURSDAY, the 21st day of March, 1895. levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the company, Room 21, No. 331 Pine Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 26th day of February, 1895, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

R. R. GRAYSON, Secretary.

Office, Room 21, No. 331 Pine street, San Francisco, California.

INYO MARBLE COMPANY OF CALIFORNIA.—Location of principal place of business, San Francisco, California; location of works, Inyo, Inyo County, California.

Notice is hereby given, that at a meeting of the Board of Directors held on the 21st day of January, 1895, an assessment (No. 26) of ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, Room No. 13, third floor, Mills Building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 6th day of March, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on FRIDAY, the 5th day of April, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

W. W. SARGEANT, Secretary.

Office—Room 13, third floor, Mills Building, San Francisco, California.

DUMBARTON LAND AND IMPROVEMENT COMPANY.—Location of principal place of business, San Francisco, California. Location of works, in the counties of Alameda and Santa Clara, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 22d day of January, 1895, an assessment (No. 7) of 12½ cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, No. 214 Pine street, room 55, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 28th day of February, 1895, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on THURSDAY, the 21st day of March, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

JABEZ HOWES, Secretary.

Office, Room 55, 214 Pine Street, San Francisco, California.

THE CALIFORNIA DEBRIS COMMISSION, having received applications to mine by the hydraulic process from W. Thomas et al., in the Central Hill Mine, Douglas Flat, Calaveras Co., Cal., to impound tailings behind stone dams in ravines; from Giovanni Rossi, in the Kate Gray Mine, near Volcano, Amador Co., Cal., to impound tailings behind log and brush dams below mine; from J. E. Newsom, in the Shealor Mine, near Volcano, Amador Co., Cal., to impound tailings behind log, rock and brush dam in Sutter Creek; from Giani Demartini et al., in the Rail Road Hill Gravel Mine, near Fourth Crossing, Calaveras Co., Cal., to impound tailings behind a dam on flat ground; and from James Slater, in his mine near Brownsville, Yuba Co., Cal., to impound tailings behind York Mining Co.'s dam, gives notice that a meeting will be held at Room No. 92, Flood Building, San Francisco, Cal., on Feb. 25th, 1895, at 1:30 P. M.

Report on the Con. Cal. & Va.

In a recent report to the directors of the Consolidated California & Virginia mine, E. S. Spring says:

As you were good enough to listen to my account of the condition of the mine ascertained during an examination made by me on January 26th and 27th, I pointed out at your meeting the exact situation of the mine as it appeared to me, which was this: That the reserves of good ore contained in the body which we have been working in for the last eight months had been greatly diminished and there remained very little rich ore, although there is much of what we would call fair grade.

I would say that the policy of economy which has ever been adopted by this company has been carried out too strictly to the letter in this case, and our very efficient superintendent, Mr. Lyman, in wishing to save every dollar for us he could, has endeavored to do all his prospecting in ore. This has been a very commendable policy on his part, for in running drifts, sinking winzes and making other openings he has made the work pay for itself, besides earning a profit for the company; but by adhering too closely to this policy he has finally reached the limit of the pay ore in nearly all directions. It is very fortunate that we have at the present time a very large surplus, amounting to about $137,000, in our treasury, and it is fortunate besides that we can immediately start out with a large proportion of this money to bring our mine into a more prosperous condition.

Now, I would recommend to the board, leaving always to the discretion of our very efficient superintendent to use his best judgment in carrying out the plan, that a more energetic prospecting of the ground out and around various floors of stopes be inaugurated. The body of ore upon which we have subsisted is a footwall body of ore; that is, it lies immediately upon the west wall of the Comstock lode in the Consolidated California and Virginia mine. I think the footwall should be our guide in explorations, and I believe that to the north and the south of where we have been stoping ore there are other ore bodies of equal size and richness. I therefore suggest as a quick, easy and economical means of solving the problem that six prospecting drifts be started in the mine, two of them north and south from the bottom of the winze on the 1750-foot level, two of them north and south from the present workings on the 1700-foot level, and two of them north and south from one of the floors above the 1650-foot level, which Superintendent Lyman may deem to be the best point and that these drifts be run along the footwall, always keeping it in sight, and these openings all be carried north and south as far as possible, and, at proper intervals, as Mr. Lyman may deem best, east crosscuts be started therefrom on the several levels and should any indications of a favorable character be encountered, that they be prospected in the directions where they look the most promising.

I also recommend to the board that Superintendent Lyman be permitted to increase the working force of the mine to any reasonable extent that he may think proper in carrying out this work. It may be possible for him to accomplish this with his present force, but to facilitate the operations which I have outlined he is to be permitted to take on the number of men that he may require, in addition to the present force.

It is my firm belief from a most careful examination of the mine that the plan which I have recommended to you will, within a reasonable time, bring the property into another state of prosperity. The Consolidated California and Virginia mine is a prolific piece of mining property; it has been given up as "petered out" by superintendents and managers many times, but as the work of exploration has continued the mine has repeatedly come into bonanza again. I have no fear but that with a more energetic prospecting of the mine it can be brought into another state of prosperity.

I would also suggest that when any ore body is discovered of the same importance as that in which we have been working the prospecting of the mine be kept well in advance of the ore extraction. The mine deserves a great deal of development work. The ore bodies occur in kidneys in the vein, and it is well to keep one or two of them in sight.

Professional Cards.

A. H. RICKETTS, Attorney-at-Law,
Mining Patents and matters before the Land Department a Specialty.
Crocker Building, Rooms 201, 202 and 203, San Francisco.

WM. GILBERT, B. S., Manager.

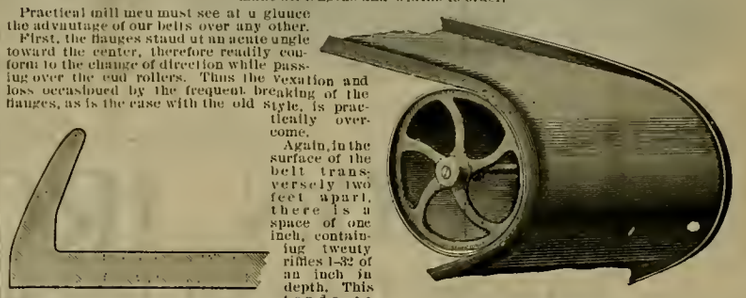
TAUGHT BY MAIL THOROUGH PRACTICAL

Blasdel Improved Concentrating Belt.
We keep in stock belts suitable for the Frue, Triumph, Johnston and Tullock machines, and make all lengths and widths to order.
Practical mill men must see at a glance the advantage of our belts over any other. First, the flanges stand at an acute angle toward the center, therefore readily conform to the change of direction while passing over the end rollers. Thus the vexation and loss occasioned by the frequent breaking of the flanges, as is the case with the old style, is practically overcome.
Again, in the surface of the belt transversely two feet apart, there is a space of one inch, containing twenty riffles 1-32 of an inch in depth. This tends to equalize the pulp and prevents it from banking on the edges, or forming channels. This riffle saves fine sulphurets and quicksilver that would escape with the tailings from a belt with an entirely smooth surface.


H. G. BLASDEL, JR., Manager,

GLADSTONE MINING COMPANY, FRENCH GULCH, Shasta Co., Cal.,
C. J. Clark, M. E., Gen'l, Supt. Dec. 12, 1891.

MESSRS. ADAMS & CARTER, San Francisco, Cal.—DEAR SIRS: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the FRUE in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for TWELVE MONTHS. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to to mention. In order to give an idea of the work they are doing here, I will state that the ore has varied monthly from $5 to $20 per ton and the tailings from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six-foot Frue Vanner too highly, and it is the only table that I would have in my mill.

C. J. CLARK, Gen'l Supt.

RISDON IRON WORKS.

Office and Works: Cor. Beale and Howard Sts., San Francisco.

Cable Address: "RISDON'S" San Francisco.

MANUFACTURERS OF

Johnston's Concentrator, Bryan Mills,
Challenge Ore Feeders, Air Compressors,

MINING, MILLING, PUMPING and HOISTING PLANTS.

The McGlew Ore Concentrator Company.

PATENTED SEPTEMBER 13, 1893. CHEAPEST, SIMPLEST, MOST DURABLE AND CLOSEST SAVING CONCENTRATOR IN USE. FRANK BARRERE, Secretary and Manager.

Can be seen in operation at the Company's works, 132 Main Street, San Francisco.

Office, 116 Davis Street.

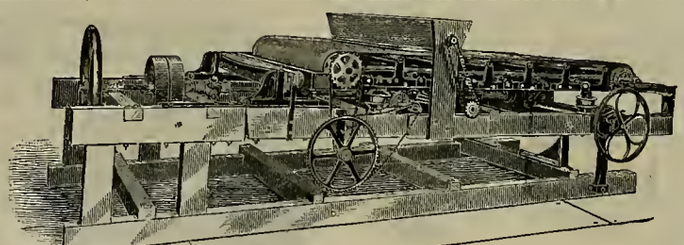
NINETY-FOUR AND ONE-HALF PER CENT
—SAVED—
ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness, combining both Side and End Motion with a Bumping Belt.

SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILST IN OPERATION.

CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE.....$350 EACH
Including prepared canvas belt 4 ft. 6 ins. wide.



FALLS MINE, IGO, SHASTA CO., CAL., May 25th, 1893.

THE MCGLEW CONCENTRATOR COMPANY:—I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years' experience with different concentrators, I believed them to be the best.

Now, after a thorough trial of the McGlew Ore Concentrator, on ores difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ores. It is doing CLEANER and CLOSER work than I had believed possible for any concentrator to accomplish.

Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 94½ per cent; from East ledge, * * * a saving of 92 per cent. The concentrator runs very easy and requires but slight attention. One man attends to rock breaker, crusher and concentrator.

You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily ecommend it to the mining public. Yours respectfully,

E. L. BALLOU, Propr. Ballou Reduction Works.

HAVE YOU A MINE? If so do not fail to see Parke & Lacy Co.'s Stock of MINING MACHINERY

AND PACIFIC ELECTRICAL REVIEW.

VOLUME LXX. Number 8. SAN FRANCISCO, SATURDAY, FEBRUARY 23, 1895. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

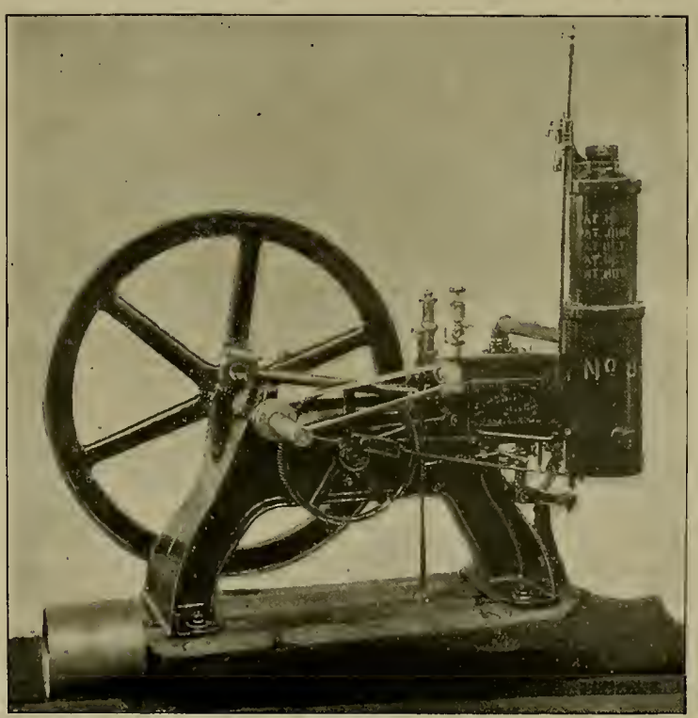
A Clear Title.

The United States mining laws recognize three distinct titles: Title in fee simple, title by possession, complete equitable title. The first vests in the grantee an indefeasible title; the second is only in the nature of an easement. The first being an absolnte grant by purchase and patent without condition is not defeasible; the second is a mere right of possession and enjoyment of profits without purchase, and may at any time be abrogated by failure of the occupier to comply with the requirements necessary to hold it. The equitable title accrues immediately upon pnrchase, for the entry entitles the purchaser to a patent, and the right to a patent once vested is equivalent to one actually issued. Sec. 2324 of the Revised Statntes refers solely to titles by right of possession, and in no way conflicts with title acquired by purchase. The latter is the lowest grade of title known to the mining laws: the next is the equitable title, which accrues upou purchase and entry; the third and final grade is the fee simple, acquired by patent, evidencing the legal title and merging it iu both the possessory and eqnitable titles. Under the pre-emption laws it may occur that the legal title may be in one person and a superior eqnity in another; this cannot exist nnder the operatiou of the mining laws, as all legal and equitable adverse claims and titles must be presented and passed on before the patent issnes, or be considered lapsed and abandoned.

The above is intended to emphasize a trite fact—that a mining claim shonld be patented. There is a variety of reasons, foremost among them being that if it is desired to sell the claim, the possession of a patent is a great deal. If the owner of tbe elaim can say "I have a United States patent," he is in vastly better position before the prospective purchasers than if he cannot. Many a good opportnnity to sell a good mine has been lost through inability to produce a Government patent. That is always a guarantee of title; there is no going back of it or behind it. Before it can be had, certain forms mnst be observed and everything proved up beyond a possibility of legal entanglement. None know this better than the men who have to pass npon the pnrchase, and when a man does buy an nnpatented mine, it is very often with the proviso that a good part of the purchase money shall be withheld nntil a patent to the property can be scenred. That is only fair, for, if there be any flaw or hitch, it will be developed during the patent-application proceedings, althongh undistnrbed and uninterrnpted possession may have been enjoyed for years. Purchasers mnst protect themselves; and the best way for sellers to do likewise is to secnre a patent. In general, if a claim is worth working or selling, it is worth patenting. A good mine with a poor title is not so readily available as a mine not so good, bnt with a clear title. Negligence, delay, carelessness, shonld not occasiou lapse of self-interest, and in the general demaud for good gold properties throughout the State it is well for every claim owner to bear these facts in mind.

The Best Gas Engine.

Herewith is depicted the Daniel Best gas engine with generator attached. This generator is part of the engine. It is the npright cylinder and connected by pipes to the main cylinder of the engine. By utilizing the heat from the exhaust is generated gas from a class of cheap, heavy oils, which could not otherwise be nsed in gas engines. From oils thus used is secnred an over-product in the shape of a lubricating oil, the valne of which—whatever it may be—is of eourse deducted from the first cost of the crude oil, which is explained in the table below of a test made recently of a Best five H. P. gas engine based upon a ten-hour run.



THE BEST GAS ENGINE.

This table also shows the test made on other oils as well as coal or city gas. By reference to this table, it will be seen the economical discrimination in favor of gas engines using crnde oils. As crude oil will not explode from any cause except when set on fire like any ordinary oil, there is further merit from an insurance standpoint. It is claimed that even if the over-prodncts conld not be disposed of, it is still one-half cheaper to nse crude oil than gasoline.

Following is a test of one of these five H. P. gas engines, rnnning ten honrs on different oils, using the generator, the results showing a reduction in the cost of operating a gas engine to a minimnm:

Coal or city gas, 1000 feet	$2 00
Gasoline (74 test), 8¾ gallons, at 14c	1 23
Domestic coal oil, 7½ gallons, at 10c	75
Santa Paula crude oil (alphaltum base), 16 gallons, at 3c	48
From this there is an overproduct of seven gallons, which is in the shape of asphaltum, valued at 3c	21
Crude petroleum (paraffine base), 13 gallons, at 5c	65
From this there is an overproduct of three gallons of good lubricating oil, which we consider equal to any we have ever used, but we will estimate its value conservatively at 20c	60

Acconding to these figures furnished by Mr. Best, the operation of these engines with erude oils reduces the cost to a minimum—crude petroleum at $\frac{1}{10}$c per honr per horse power, Santa Panla oil about ½c per hour per horse power, domestic coal oil 1½c per hour per horse power, and on gasoline 2½c per hour per horse power.

"What does it cost to produce an ounce of silver" is a question that has again been started going the rounds. An English authority gives the indefinite data of "over four shillings an ounce." That, certainly, appears to be sufficiently obscure to pass nncontradicted. Still, in extenuation of that vague transatlantic estimate, it must be confessed that an exact answer to the question is difficult to give, as so many factors enter into the eqnation, some of them extremely difficult to determine. Where silver and silver alone is prodnced; where the ore yields a large percentage of gold, where "the lead pays for the mining," there must be large allowances for the necessary difference in cost of production. Then, too, is to be taken iuto consideration the amount of necessary dead work, the investment in machinery, varying cost of snndries, all of which enter iuto the question. The fact that so many straight silver propositions have shut down emphasizes that at present qnotations they have ceased to pay. This is probably the most practical evidence of cost that can be fnrnished. Where silver has been merely a "by-product" its cost has been reckoned as low as five cents an onnce. Where it has been produced from an assessed, non-dividend paying mine it has been shown to cost over $2.25 an ounce. In the old days on that part of the Comstock working in bonanza an ounce of fine silver was reckoned to cost thirty-eight cents; the mines working in barrasca made the silver they yielded cost $2 an onnce. It is believed that during '91 the average cost of an onnce of silver mined in this conntry was abont eighty-four cents. The improvement in silver processes has not kept pace with that in gold methods. Taken all throngh, it is probable that anything short of eighty-five cents an onnce for fine silver makes its mining, in general, an unprofitable pnrsuit.

The taxation of mining claims in Colorado is being discussed. It is in order to observe that nnpatented mining claims are now "taxed" annually $100, except when that law is suspended. The tax does not go to the government, but the principle is virtually the same.

The Siberian newspapers announce the discovery of rich and extensive gold fields along the upper reaches of the rivers Neya, Nina and Uibat, in the province of Yeniseisk, East Siberia.

The war over railroad transportatiun rates from the coal fields to Chicago is the means of landing soft coal in that city at a lower cost than ever before—$2 per ton.

"Everything is cheaper these times," says a city contemporary. How about gold?

Earnings of Labor in 1890. Russia's Metal Resources, 124. Where Cash is Scarce; Market for American Woods, 125.

REGARDING the proposed suspension of assessment for '95, the general consensus of the mining community is against it. It would be a mistake to repeat the suspension act of '93 and '94.

THE Colorado smelting combine has gone to pieces, and hereafter each smelter will act independently, the constant contest between the ore seller and ore buyer assuming a phase more favorable to the former.

REFERENCE was made last week to the injunction bill in the State Legislature, which gave hydraulic miners the same standing in law enjoyed by other people in other pursuits—no more, no less. It passed the Senate, was beaten in the Assembly, but was reconsidered and passed to second reading; hence will now in all probability become a law. The success of this measure is largely due to State Senator Ford and Assemblyman Thomas.

A MONTANA CONGRESSMAN has discovered an unrepealed law passed in '57, ordaining that certain denominations of Mexican silver money be received at the United States Treasury at fixed valuations, and hopes to make it possible by legislation to send silver to Mexico for coinage, bring it back here and get the value for it under the law at the United States Treasury, thus indirectly securing free coinage of silver. The validity of the law is beyond dispute, but the official cessation of Mexican mintage of the coins designated in the statute, will render nugatory the attempt. The dies for those coins were destroyed ten years ago.

RECIPROCITY with Mexico is of present importance to the United States. The productions of the country are different. Mexico is a country of raw material; ours is a manufacturing country. Mexico has 15,000,000 people engaged in silver mining, sugar growing, coffee growing, etc., who have money to pay for improved mining and other machinery, and manufactured articles of every kind. Mexico is not naturally a manufacturing country, but it is a natural market for the United States. It must be cultivated: the needs, tastes, even whims of the people should be catered to; what is worth having is worth asking. And because of this, the approaching Mexican Exposition is of considerable commercial importance to this city and State. There is a good feeling between the two countries; our southern neighbor is rich and prosperous, and anything and everything that can create and continue commercial relations and good will should be put into operation.

ANOTHER detachment of the California party that left here last May for the South African mines has returned. They tell the same story: poverty, extortion, very low wages, scarcity of work, inferiority of the country as compared with California for mining and woeful privation of many there. It is the universal verdict of all we have seen who have been there that, unless a man has assurance of a good position at a very large salary, he is unwise to seriously contemplate going there. Of course, brains are never at a discount anywhere, and a clever man will ultimately get a foothold; but the same expenditure of skill, knowledge and energy that would admit of his making a meager living there would give him a far better mode of existence in California—the most favored gold mining region on the globe. The PRESS early received positive evidence regarding the undesirability of indiscriminate migration to the South African gold fields, and has reiterated the information. A multitude of interior papers have steadily advertised the cheap passage rates announced by a shipping firm in this city; and this, with the glamour cast over the fact that a few first-class California miners who had considerable State reputation have got princely salaries there, has naturally acted as an incentive to many to try their luck there too. But the facts are as so often stated in these columns, and time tends more and more to confirm them.

How opinions change with changing circumstances is well illustrated in the case of certain editorial writers in Colorado. Eighteen months ago they wept over the silver depreciation and declared the bottom had fallen out of that State. According to them one of the greatest of our American commonwealths was doomed to depletion, and nothing was left but to mourn over the grandeur of the past. But the sturdy miners of the Centennial State uncovered its golden treasure, and, finding no profit in silver mining, developed the gold mining industry. Now, the same men who talked so dolefully over the silver outlook have gone clear over on the other side, and say silver is no good anyway; that gold is the thing, and that Colorado would be a loser by the free coinage of silver. Of course, the truth lies between. Nothing but the indomitable spirit characteristic of the miner could have redeemed Colorado from the depression of '93, but because the gold yield of that State so far exceeds their anticipation does not justify Colorado writers in decrying silver. Apart from other considerations there is a requisite consistency in expressed thought that fails to sanction such complete change in opinion. But had any writer outside of the State in '93 said half as much about the relative value of gold and silver mines as those alluded to are saying now, how he would have been held up as an enemy of mankind in general, and the foe of silver in particular. The State of Colorado is to be congratulated on her happy solution of the industrial problem more than upon the vacillating policy of some of her citizens, who exemplify by their published statements the difference between those who work and those who only talk.

As To California.

With all the talk about the sales of mines to Eastern syndicates, who knows of any considerable sum of money actually paid by the Eastern men last year? We venture to say the total paid for Western mines—not stocks—did not exceed a quarter million dollars. The present year promises to do much better. It starts off with one cash sale we know is made—the Iron Mountain group of California. Among others who were interested in the sale, were N. F. Cleary, formerly of Leadville, and Hugh McDonnell, of Montana, who is well known in Denver. A good, nice part of the purchase price of $300,000 was paid in cash last Thursday. Boston and New York parties were the purchasers.—*Denver Mining Industry and Tradesman*, Feb. 14.

Eastern men put a good deal of money into California gold mines last year. The excerpt above is not in accord with the facts. Among the large sales of California gold mines reported made in '94 to "Eastern men", may be cited the Somerville Con. Gold mines, consisting of the Lena, Bellflower, Young America, Seminole, George Worcester and Buckeye, in Tuolumne Co., sold to D. H. Cole, of New York City, for $1,000,000; the Burton group, on the Robinson Ferry road, one mile north of Tuttletown, Tuolumne Co., sold to Montreal men for $140,000; the Mountain View in Fresno Co., sold by A. Wambold to Chicago men (Chicago is reckoned "East" out here.) for $40,000; the Gold Ridge Consolidated, comprising four quartz mines, and 1600 acres hydraulic ground to L. Barstow and W. Pumfort of New York, for $35,000, the Chapparall mines near Angels Camp, Calaveras Co., sold to Mathers & Jackson of New York, for $400,000.

Besides these there were numerous other sales, principally in central and northern California, of mining properties, drift, placer and quartz, involving sums from $5,000 to $2[illegible],000, wherein a large part of the purchase money was furnished by Eastern men; the Manhattan and Chemical banks of New York being the intermediary in one $450,000 transaction in Sierra Co. Besides "Eastern men", the past year saw considerable capital from Colorado, Montana and Utah judiciously invested in California gold mines, yielding and to yield a handsome return. British and French capital to the extent of at least a million dollars also found investment in this State in gold mines in '94.

The Jones Bill.

The Jones bill is manifestly unsatisfactory to those who favor the coinage of silver at the ratio of 16 to 1. It provides that holders of silver may have it coined into standard silver dollars, receiving its equivalent therefor, measured by the metal's market price in New York at the time of its deposit in the mint. At 60 cents an ounce that would mean a ratio of about 34 to 1, which from a free coinage of silver point of view is absurd.

In discussing the question a usually astute Utah contemporary declares that the passage of the law would immediately send the price of silver up to $1.29 per ounce. "'Tis a consummation devoutly to be wished." But will it? Experience says "No." The gentlemen who, when silver was being bought and coined to the extent of 54,000,000 ounces a year, were able to hammer the prices down from $1.18 to 81 cents an ounce, would be able to make or mar the market at their selfish pleasure under the Jones bill. As a constant and consistent advocate of silver the PRESS believes that the Jones bill would not open an American silver mine nor aid in solving the present financial difficulty. Pattering, subterfuge or evasion has about worn out the patience of the country. There should be no half-way measures. It must and will come to free coinage of silver at the ratio of sixteen to one, and nothing else will satisfy the country or afford necessary relief.

Well, Well!

Although California is the oldest mining camp in the west, it is way behind the times in improved methods of mining and milling.—*Deadwood Pioneer*, Feb. 15.

The author of the above omits to state whether he knows the assertion to be a fact, or whether it is just his own private opinion. If he assumes it is a fact, he will please establish proof. If it be simply his belief, while he has, in general, the right to be wrong, yet in this case he abuses the privilege. As the pioneer in gold mining and milling methods, California has originated about all the successful principles in actual practice; the miners of this State are in all respects fully up to and in several respects ahead in modes and methods of mining and milling gold ore; the latest, up-to-date processes are in use all over the State, many of them California productions, and when a competent man is needed in any part of the world to superintend or successfully manage large mining enterprises it is to California that the owners or directors turn—and they usually find the talent, skill, experience and ability needed. For these men they pay from $5000 to $60,000 a year. "They come high, but they must have 'em."

The South Dakota scribe who got off the above squib might be pardoned for his ignorance, but his stupidity cannot be condoned.

THE Committee on Mineral Lands, appointed at the last session of the California Miners' Association, report very satisfactory progress. The famous or infamous "clear list 54," covering nearly 134,000 acres of valuable California land, and once certified to as correct by the Government examiners, is to be published, and miners will have a chance to file protests. This list embraces lands in Nevada, Placer and El Dorado counties, and is of interest to every miner in those counties. List 22 in the Los Angeles district and list 25 in the Redding and Marysville land district have also been withdrawn, and there is a general suspension of Government haste in patenting lands to the railroad companies. The Hartman bill leaves California out, but a bill forfeiting all lands granted to bond-aided railroads has been reported favorably by the committee to whom it was referred, and approved by the Secretary of the Interior. As usual, Senator Stewart, of Nevada, is fighting the effort to secure justice for the miners and trying to aid the railroad side of the case.

Concentrates.

GOLD commands 3⅛ of 1 % premium.

THE Morning Star Mining Co. has declared a $4 dividend.

THE Mammoth (Arizona) mill and mine start up this week.

COLEMAN & TURNEY have bought the Angel's mine, at Angels.

THE PORTLAND G. M. Co., of Victor, Colorado, has declared a $30,000 dividend.

THERE are upwards of 400 men, including teamsters and ruwhiders, working in the Slocan.

THE number of men employed in the Little Johnny, Colorado, mine is 220, and the output 220 tons daily.

RYAN BROS., of Cheyenne, have bought a half interest in the Lost Horseshoe mine, near Indio, Cal.

THE only mine now in operation at Mullan, Idaho, is the Grouse, on which but three men are employed.

THE mill on the Empire mine near Copperopolis has been completed, and in a short time will be started up.

DURING January twenty-seven mining companies in the Rocky Mountain region paid $788,000 in dividends.

THE *Echo* wants it understood that Angel's Camp, and not "Angels," is the name of the town where it is published.

T. J. REGUA has leased the borax works in Saline valley, Nevada, abandoned by Messrs. Stoutenborough & Milner.

THE Anaconda company will begin next month the erection of a refinery, etc., at Great Falls, Montana, to cost $2,000,000.

ACCORDING to the Leavenworth, Wash., *Journal*, "considerable platinum" is washed in the gold gravel thereabouts.

EIGHTEEN men are reported making good wages on their own account at Montgomery, Ivanpah district, San Bernardino Co.

ALUMINUM has been discovered again, this time in Utah, "in volcanic slag," which is a decided metallurgical phenomenon.

AT the new gold camp six miles from El Dorado canyon, Nevada, Flood and Mackay have thirty men developing their property. A mill will shortly be built.

FROM Vanderbilt, Cal., comes a description of a unique stamp mill, built by Mr. Brown, entirely of wood except bosses and shoes, and operated by horse power.

DIVIDEND No. 1 of the War Eagle Mining Company has been declared payable at the offices of the company in Spokane, Wash. Amount $30,000; six cents per share.

EVERY conceivable method of placer work, from the rocker and snipe to the Kent washer and sluice, is being utilized in getting gold from the bars in Colorado canyon.

THE Old Glory mill at Oro Blanco, Arizona, is said to be taking $100 off from the plates every twelve hours, and $100 in concentrates, making a total daily yield of $400.

THE Golden Valley Mining Company has been incorporated at Portland, Maine, for the purpose of engaging in gold mining in the Ures district in Sonora. The capital is $100,000.

THE Green Mountain mine, in the Murchie ravine, Nevada Co., has been bonded by J. W. Straw, late foreman of the English Mountain mine, who is backed by a Colorado company.

FOUR HUNDRED THOUSAND DOLLARS is the announced price paid for the Blair mine to J. J. & Wm. Smadeke at Smith's Flat, near Angels—$30,000 down, and the remainder later on.

IT is said that the Tacoma smelter is now guaranteeing mine owners that payments for ore will be made in gold, provided the yellow metal sells at a premium before the end of 1895.

RAIN has evidently fallen in Arizona. The *Prospector* says: "This is a splendid year for ducks and placer miners; placer gold is coming in from every quarter and ducks from every valley."

THE Prince mine, in the heart of the town of Altaville, Cal., shows a four and a half foot vein, and is reported to yield well in free gold. No accurate value of the rock has yet been secured.

A BILL has been introduced in the Montana State Senate providing for the establishment of a uniform system of signals for use in all mines where the shaft is seventy-five feet or more deep.

THE Somerfield mine, owned by C. O. Barker of Banning and Fish & Son of San Bernardino, near the old Dos Palmos stage line station, San Bernardino Co., has been bonded for $125,000.

W. C. WYNKOOP of Denver, last week closed a sale on which he had been engaged a year, of mining property in Calico district, San Bernardino county, for $75,000. Boston men are the purchasers.

EXTENSIVE sulphur mines situated in Lower California have been located by Anthony Godbe, the claims having been accepted by the proper department of mines of the Secretary of the Interior.

COLORADO SPRINGS reports that the Mollie Gibson company will pass its February dividend. The mine is only producing 40-ounce ore at this time, and expenses of the past month consumed all the output.

THE Nevada *Sentinel* says "there is not a man in Eureka county who has an income of $4,000 a year." The income tax does not affect the people of the Base Range. The price of silver is too low for that.

THE *Echo* hears that the Sawyer claim, situated on the Dead Horse lead, Angel's Camp, has been bonded by the Utica Mining Co. for $34,000, and that a deed will issue for the property in June next.

AT SONORA last Monday, in the Golden Gate mine suit, the ninety-one special issues were all decided by a jury in favor of E. C. Loftus, the plaintiff, thus deciding that the mine was not a corporation but a copartnership concern.

A TACOMA dispatch says: "If all indications are not at fault the famous Lost Rocker mine of Alaska has been found." All famous "lost" mines in all localities are always "found" when the snow lies the deepest, but the find rarely materializes later in the year.

THE Seattle *Press-Times* says: "Already there are many more men in Juneau and on Douglas Island, immediately opposite, than can be given employment at the Treadwell, Boston or Nowell mines, vacancies in any of the three companies rarely occurring among the white operatives. This is due to the fact that all through Alaska, at both mines and canneries, the "siwashes"—native Indians—are employed to do the rough and more laborious work, white men only being employed when skill or technical knowledge is necessary."

AS a matter of urgent necessity, a bill was introduced in the House last Thursday appropriating $20,000 to pay the expenses of the United States Debris Commission. It is possible that this session it will be appended to the civil appropriation bill, and so go through.

WITH surprise not unmixed with doubt it is read in the Yuma *Prospector* that the heirs of the late Senator Fair have sent to Yuma a detective to hunt up information detrimental to their father's character during his visits there in the fall of 1892 and winter of 1893.

FOR the month ending December 1st, '94, the gold yield of Western Australia was as follows: Coolgardie, 14,633 ounces; Murchison, 7,361 ounces; Yilgarn, 1,319 ounces; Kimberley, 194 ounces; Dundas, 100 ounces; Pilbarra, 20 ounces; total, 23,628 ounces; value, £89,787.

THE American company which recently bought the Santo Domingo gold placers, in the Magdalena district of Sonora, have already spent $100,000 in road making, machinery purchases and other preliminary work. The ground to be exploited comprises 200 claims of a hectare each.

THE Crescent Gold Mining Company has filed articles of incorporation with the Montana Secretary of State. The capital stock is $250,000. The incorporators are R. B. Henderson, J. S. Sherburn and W. E. Horton. The company will operate the Crescent mine, in Park district, Jefferson county.

IT is no uncommon thing, says the *Echo*, to hear of parties receiving a patent for a homestead and then in a short time therenfter developing a mine on the land, or leasing a portion of it for mining purposes. There are a few such cases in Calaveras county, and, probably, in Tuolumne and Amador.

A. HANAUER has nearly completed his annual report for the government of the mineral output of Utah for 1894. The report shows, contrary to all prophecies, that the silver production did not increase during the year, but was substantially the same as that of 1893. The gold production was heavily increased.

THE Tucson, Arizona, School of Mines is about to put in a car-load of mining machinery, including a crusher for fine work; a 5-stamp mill, with 600-pound stamps, feeder, plates and all appurtenances; a 3-stamp mill, with 250-pound stamps, for treating small lots; a sample grinder and automatic sampler.

CHICAGO firms have offered to provide the capital necessary to bring water on to the gold bearing benches of the Anglo-American gold mine claim on the Similkameen river, provide all the machinery and put the enterprise on a sound footing. The Anglo-American company are considering the proposition and conditions.

THE War Eagle mine, Trail Creek, cleared $25,000 last month, after paying all expenses, including new buildings, etc. The War Eagle people were inconvenienced on account of there being no custom officer in Rossland, so they made application for one, and guaranteed his pay. Already the office is self-sustaining.

CRITICISING a recent article about South African mines, a Colorado subscriber says that Mr. Webber, the superintendent of the Crown Reef would not exaggerate the value or amount of the ore therein, and that the ore in the Little Jonny will average $50 per ton, and stating that the way it is here spelled is the correct orthography.

IT is reported that the London & Cripple Creek Reduction Co. has been organized to build a smelter at Colorado City with a paid-up capital of $650,000, and that the company has secured an option on fifty-four acres adjoining Colorado City, including the iron furnace and glass works, the former of which is to be turned into a smelter.

AN Arizona miner is reported at work near the summit of Mt. Union, one of the highest mountains in that section, with a rocker taking out placer gold. Water from snow is to be had sufficient for rocker work there at this season of the year. It is an Arizona peculiarity that placer gold is as liable to be found on top of a mountain as in the bed of a creek.

FLATTERING REPORTS are being received from a new gold find on the line of the Atlantic and Pacific road, about three miles west of Ibex. The croppings were hauled to the Ibex mill, where it yielded $12 per ton. From these prospect holes they are now taking out ore that runs $60 in gold to the ton. The owners of the Ibex property are chiefly interested in the new find.

JOHN POPEVALE, a miner employed at the Rawhide mine, Tuolumne Co., last Tuesday fell from the skip at the 500-foot level, and was instantly killed. He and another were in the skip at the 400-foot level. One of them gave the engineer the wrong signal and he sent the skip into the sump. As he was signaled to hoist, the unfortunate man fell off, his head being crushed and his neck broken.

THE Washington State land officers have received a decision from the Commissioner of the General Land Office affirming the local officer's decision in favor of McBride in the famous contest case of the State of Washington against John G. McBride, involving a valuable school section in the city of Tacoma. McBride based a claim to the section on the alleged mineral character of the land, in which he has been sustained.

THE Juneau, Alaska, *Record* figures that the Treadwell stamps crush, each, 110 tons every twenty-four hours. They each weigh 850 pounds, and make ninety blows per minute. Were mechanism devised to make them strike 900 blows per minute they couldn't each work 110 tons daily. A stamp mill that crushes three and a half tons to the stamp every day is doing more than the average. Probably 110 tons per month is meant.

PUMPING the water out of the Oro Fino, Cal., mine, begun in December, has just been completed. The mine has been worked to a depth of somewhat more than 300 feet, and the work of pumping out has been a big job. There is a good-sized ledge exposed, and some of the rock is very rich. The first mill on this ledge was built in 1862. In 1866 the property was purchased by Virginia City parties, and was worked for several years with good results.

THE case of Silas F. King vs. the Amy and Silversmith Mining Company has been sent back to the district court of Silver county, Montana, on a remittur from the United States Supreme Court. The case was tried in the district court there two years ago, and a decision rendered in favor of the plaintiff. It was then appealed to the State Supreme Court with a like result, and from there to the United States Supreme Court, with the above outcome.

THE American Falls Canal and Power Company has incorporated at Boise, Idaho, capital stock $500,000, to build and operate a canal near American Falls, in Idaho, for mining, milling and agricultural purposes, to be sixty feet broad, and carry four feet of water, about fifty miles long. The preliminary surveys have been made, a practical route found, and the final location will be made at once, and the work of construction commenced as soon as the weather will permit.

GEORGE WEBBER, who since '88 has been superintending operations at the El Callado gold mine in south-eastern Venezuela, is off via this city for the South African gold fields. He says that when the Rothschilds bought the mine in '88 for $5,000,000, it had already yielded $18,000,000, and since then has produced $7,000,000, besides the millions that he says have been stolen by the Jamaican natives working in the mine. This gold mine, which, if all asserted be true, is the richest gold mine in the world, is considered to be about exhausted.

THE Colorado or Minas Prietas camp in Sonora, Mexico, is reported by F. A. Drake, to be one of the greatest gold camps in the world. He says that the camp has seven mills, running day and night. Some of the ore is exceedingly rich. The Yuqui miners had stored away a total of twenty-six pounds in the Colorado mine, which they were trying to bring to the surface. They were caught with it. The value of the ore was $60 a pound. The company are now said to be contemplating building a branch railroad to Torres, a distance of seventeen miles.

BANTA & WINK, Port Orford, Or., claim to have successfully solved the problem of separating the gold from magnetic black sand by means of a system of sluice boxes "saturated with a chemical crystal that attracts and holds the gold," the solution being "charged with a magnet invented by us, the crystals being repulsive to iron." They say: "We save 90 per cent of all gold in black sand or gravel, no matter how fine the gold may be." These are very sweeping claims, and, if substantiated, will be of surpassing importance to many who have long been baffled in attempts to successfully work black sand deposits.

The Idaho *Statesman's* Silver City correspondent mentions the fact that in one of the mines there the exhaust plan of ventilation has been adopted. This is the only method of ventilation where ventilation has to be produced by artificial processes. The old idea was to drive fresh air into the face to supply the men working there, but this resulted in filling the works with the smoke and gases. By the exhaust process the gases are drawn into pipes at the face and taken out of the mine, leaving nature to fill the vacuum with pure air. This method is particularly useful in running a long tunnel. Under the old method men were sickened by walking through the gases driven back from the face, but, with the gases and foul air taken away from the face and carried out through pipes, there is no part of the tunnel where the air is not perfectly pure. The wonder is that this mode of ventilation should not have been devised sooner than it was; and now that it is in use there is no excuse for continuation anywhere of the old man-killing method.

IN southern Oregon, where most of the mines of the State are located, the bill introduced by Representative Smith of Josephine, to change the mining laws of the State, is unpopular. It is claimed it would unnecessarily place many impediments in the way of the development of Oregon's placer mines and seriously injure that important industry. The impounding of tailings, which is required by the measure, is one of its specially obnoxious features. The miners say Representative Smith's bill will probably suit R. D. Hume and some farmers living along the streams in which the farmers run their tailings. Hume threatened to shut down mining in southern Oregon because the people objected to him capturing all the fish that wanted to go up the river. He said the miners were shoaling the mouth of Rogue river. The miners do not want any such bill, and it will be the beginning of endless litigation and the shutting down of gravel mines in Jackson and Josephine counties.

Personal.

H. B. MURRAY is back from a two years' trip through Mexico.

THOS. T. LANE has returned from this city to the Utica mine much improved in health.

MR. D. W. BALCH, formerly assayer in the United States Mint, is at Sydney, Australia.

Ex-Gov. WILLEY has sold his extensive mining interests in Idaho, and will locate in this State.

GEO. R. SMITH, former president of the Gold Hill, Nev., Miners' Union, is reported dying at Reno from miner's consumption.

RALPH NICHOLS denies the statement so generally circulated that he has been appointed superintendent of the De Lamar mines, Nevada.

THOS. COUCH, of the Boston and Montana Mining Co., and principal owner of the Merced Gold Mining Co. property, is visiting Coulterville, Cal.

W. H. JAMES, manager of the Omaha & Grant smelter, denies that his company has any intentions of erecting a smelting plant at Guaymas, Mexico, or Vancouver, Wash.

E. R. ARADIE, formerly superintendent of the North Star mine at Grass Valley, is now superintendent of a gold mine at Johannesburg, South Africa, at a salary of $10,000 a year.

MR. I. B. HAMMOND, of Portland, Or., is in the city. He has completed arrangements with the Fulton Engineering and Ship-Building Works to build his new five-stamp mill, which he is introducing.

J. R. DE LAMAR, the "Monte Cristo" of Idaho, is a native of Holland. He is sized up by a local newspaper as small in stature, with large features and red hair, and has been a sailor, a glue workman, a bartender and a butcher. As he is now a millionaire he has given up the other jobs.

Obituary.

WM. GWINN, SR., died recently at the Vacas silver mine, near Muleros, Mexico, where he had superintended affairs for the last eight years. He was a California pioneer, well and widely known, and built the telegraph lines in this State between Auburn and Grass Valley.

A Paternal Scheme.

SHALL THE GOVERNMENT OWN OUR RAILWAYS? By Eugene D. Mann. Pamphlet, 16 pp. Price, 20 cents. Town Topics Publishing Company, New York.

The author answers his own question in the affirmative, and after disposing of all objections to governmental ownership, although seeing some financial difficulties in the way of raising the six or seven billions cash which he fixes as the value of the $10,500,000,000 of railway securities, he elaborates the following plan for acquiring the nearly 180,000 miles of railway now in the United States:

Let all the railways, either voluntarily or by government compulsion, unite in a common trust, with the government, represented by a commission, as trustee. In order to effect this union upon an equitable basis, the President, the Speaker of the House of Representatives and a practical railway man to be chosen by these two shall act as a committee to select and name a "commission of appraisement." This commission shall consist of twenty-five members, chosen as follows: Five railway men, five bankers, five merchants, five lawyers and five expert accountants, each to be thoroughly representative of his class. They shall serve for the period of one year, in which time it is expected that they shall complete their work, at a salary of $25,000 each. Each member shall be entitled to one able clerical assistant, at a salary of $4000. This will cost for the year $725,000, and the government shall be reimbursed later on by the consolidated railways.

The commission shall divide itself, by lot, into five sections of five members each (one banker, one railway man, one lawyer, one merchant and one accountant to each section). It shall also divide the country into five sections, corresponding with the number and extent of railways. Then, again by lot, a section of the country shall be assigned to each section of the commission as its field of work.

An exhaustive examination of all railways shall thereupon be made, with the view of ascertaining their rightful value. The extent and condition of material property shall be carefully inventoried. Debts, funded and unfunded, as well as accumulated surplus and sinking funds, will be scheduled. Past business and future prospects will be fully taken into account, in order that their earning capacity may be justly estimated. All the elements that tend to determine or influence railways' assets, both present and prospective, shall be given consideration and proper weight.

It is reasonable to infer that in this manner the real selling value of a railway may, without prejudice to either seller or buyer, be arrived at. A comparison of this appraisement with the outstanding securities of each railway will, in due time, enable the commission to set a correct exchange value upon the latter.

The findings of this commission of appraisement shall be accepted as final by both the government and the railways. We will assume that the total valuation thus obtained will amount to $7,000,000,000. The government will then prepare and issue, as trustees, its certificates of future participation in a total of this amount. The owners of previous railway securities, according as the value of each has been fixed, will receive, in lieu thereof, these new certificates pro rata of their holdings. The character and denominations of these certificates will have been determined by the commission of appraisement. They shall be freely negotiable, being made to bearer, with a provision for registry if desired. This, it may be incidentally remarked, would doubtless put the larger share of them, sooner or later, into easy circulation and make them as available for currency as greenbacks, and with an equally sound and acceptable basis.

The government would assume no obligation of redemption other than the duty to, at any time, through its treasury and sub-treasuries, issue new certificates in place of old or mutilated ones. The knowledge that they represented such vast, permanent and profitable wealth, administered by an absolutely responsible trustee, would be all the guarantee the public would demand. The property would exist and be maintained forever; the trustee never dies, and the business and earnings would go on as long as the nation survives. Neither bonds or greenbacks present better credentials.

Having thus placed itself in possession of all railways, the government will proceed to operate them, as trustee for the certificate holders, upon a plan outlined in the following pages.

The net earnings, after providing for maintenance and repairs, shall, to the limit of five per cent upon the whole issue of certificates, be paid over semi-annually upon presentation as a dividend to the certificate holders. All earnings in excess of five per cent shall belong to the government as compensation for its services as trustee, thus acting as an additional incentive to profitable management.

It is expected that the ship canal between the Baltic and the Black sea, which is one of the greatest modern strategic and commercial works, will be opened for traffic by the close of the present year.

Unemployed Ironworkers.

It is possible there are more iron men with nothing to do in Chicago than idle mechanics in any other trade. All over the city the grim buildings whose funnels have been scorched and eaten by the blast flames are half deserted, and the white sands which shape the pillars and engines and pigs and rails and bars have not felt the sting of the yellow metal for a year. The weird places with shambling roofs and blackened sides, where have worked big armies of bare-armed vulcans, are now silent save for the clash of a few hammers that tinker on custom orders, or the songs of the polishers who oil and brush the rust on the rollers that have nothing to roll and the cranes that have nothing to lift. The molders and machinists, the big honest fellows who have skill in guiding intricate contrivances and have a sure knowledge of all the possibilities of iron, find their occupation half gone, and they join the sailors in the lament for the good old times of long ago, when the trades were young and the people few.

It is an undeniable fact that the ironworkers are having a hard row. The products of the foundry and machine shops are only in demand in the seasons when the factories are crowded and capital is feverish to venture into new fields, with new inventions. This demand fires the blast, puts all the pattern makers into activity, drives the machinery men into the night, and the trade finds itself rich and prosperous. This is not its condition this winter. The summer trouble closed many foundries, it checked investment, it canceled many contracts already upon the blue prints in the drafting room, and now that winter is here only a fraction of the employes is turning the lathe or heaving at the giant pots before the spouts of the ovens. Placards are nailed to the office doors, in plain black letters, that no molders are wanted under any consideration, and the doorkeepers demand a card to assure that the caller does not seek the master machinist in search of work.

One of the most promising features in the prospect of the ironworker is the increase in the foreign work in this town. It has only recently been developed that the Chicago foundries can teach all the world a few tricks, and in consequence their products are being shipped around the globe. Ocean boats are chartered outright, and deep in their holds are sunk beams to hold up the sides of the mountains over the Russian mines, or pumps and crushers and diggers for the diamond fields on the end of Africa. They land engines and presses in Australia, and pumps and mills for ores in Brazil. They do this readily, giving the item of competition far less consideration than European ingenuity, which quickly imitates the American notion. They dread more the eyes of the curious German, who wonders at the new wrinkles the Yankees are setting up in his own country, and his speed in reproduction, than they do the tariff on or off.

This branching out was one result of the World's Fair. The exposition filled the city last winter with men who were piteously unable to help themselves, but this year it has proved the salvation of the men who live by iron. It told the story of Chicago's possibilities to all countries, and all the foundrymen who made exhibits find their territory has been enlarged from city and county to State and nation, and then to the world. But for this, half the men now at work in this trade would be idle, and the poverty twice as great. There are eleven hundred men in a single shop across the river who are heaving and tugging at mammoth castings that go into the mines in the Zulu country, and this is but a sample. Charles E. Billin declares such contracts have been the salvation of the local business, godsends to the mechanics. They have kept one thousand men in places ample for two thousand, and have made places for one man in the four. There has been a dearth of city work, and until Mayor Hopkins took charge the Eastern firms had the preference in the bidding. It thus happened that with the army of machinists and molders empty-handed at home, the engines, pumps and bridges and structures of iron and steel, directly and indirectly built by municipal authority, have drawn their material from other centers.—Chicago Herald.

Enlivened by Gold.

Eighteen months ago, says the Denver *Republican*, it was thought by many persons that Leadville would be ruined by the decline in silver mining which was then seen inevitable. It was feared the famous camp would soon become almost dead and that property in general would depreciate in consequence of closing the mines. To-day Leadville is one of the best mining camps in the United States, and probably the most prosperous town in Colorado. Instead of depression, prosperity characterizes every line of business except it be some form of silver mining. The people are full of hope, and confidence is expressed in every countenance. There are no men in Leadville who grumble at its condition. All are confident of the future and assert with pride that they have the best town in the West. This wonderful condition of affairs is due to the working of gold mines and the sinking of shafts in search of more ore.

To Tax Mining Claims.

"A prominent mining man" tells the Denver *News* he has discovered a remedy for the financial stress under which the Legislature is laboring. His idea is to tax mining claimants $2 per year upon each claim held by the individual or company. A man holding five claims would be assessed $10 a year and the individual holding twenty-five claims would be obliged to pay $50 a year.

"I have been looking up the matter," said he, "and it is astonishing what a great source of revenue the State has been overlooking. At a moderate estimate there are 500,000 mineral locations in Colorado, which escape taxation. Each mineral claim is 300x1500 feet in area and embraces 10¾ acres. The claimant, in fifty cases out of one hundred, does not live in Colorado, but is simply holding on in hopes that somebody else will spend money in development in the region, and thus make the property valuable. It is possible that a man may do five or ten days' work on a claim in the course of a year, and announce that he has performed the requisite development work. In many cases no work is done at all, and yet the claimant will stand any bona fide prospector off with a shotgun if he enters upon the property. Why, I know of a group of claims that have been held for ten years as a speculation and practically no development at all has been made."

Somebody suggested that people of the mining counties would indignantly protest against any tax on prospects.

"Let them protest," was the reply.

"It is nothing but absolute justice that the properties should be worked or they should be thrown open to new comers. The farmer with his little patch in the valley is taxed for every dollar of improvement. The bona fide miner is taxed on the output of his mine or on the surface improvements, but the fellow with a shotgun is never touched. A man should be obliged to carry on business or quit. Many of the mining counties are asking for appropriations to build road or bridges. Let them assess the holders of mining claims and they will have money to build all the roads they want. Why, these people actually levy tribute on Denver to put into roads and bridges."

A listener, who evidently sympathized with the speaker, called attention to a reform which he desired to see carried out. "There is a tract of land in Costilla county," said he, "known as the Trinchera estate. It is owned by Dr. Bell, of Manitou, General Palmer, of New York, the heirs of the late Governor Gilpin and others. The tract has many valuable gold placers; it has iron mines, timber and stone. In 1881, 10,000 tons of magnetic iron were shipped from the estate to Pueblo, upon which the owners of the grant got a royalty of fifty cents a ton. Gentlemen, if you want to be treated to a surprise look up the reports of Costilla county and see how much this land grant contributes in taxes to the county."

An old timer from the Black Hills region told how the camp was made prosperous years ago. "At the very start," said he, "the miners held a meeting and discussed at length the amount of land that any man or company should be allowed to locate. The plan that was adopted proved to be the wisest action ever inaugurated in the district. It was the vote of the assembly that a man who discovered a lode could have the right to file two claims—one upon the lode and one as a reward for the discovery. All future comers were limited to one claim. There was no law for the action, but no man dared to run counter to the will of the community and gobble up an entire mountain."

The Black Hills man said further that in those days there were no disputes over apexes and side lines. A miner's claim extended straight down toward the center of the earth.

Wagon Bows.

The manufacture of wagon bows, such as are used for stretching canvas over wagons, is quite a little industry of itself. St. Louis can boast of turning out more of this product than any other place in the country. Lloyd G. Harris, president of the Lumbermen's Exchange, said recently that the fall had been a particularly good season for trade in wagon bows. The failure of crops in several Western States last summer on account of the drouth caused a boom in this trade. In fact, the emigration movement can be measured by the orders for wagon bows. Mr. Harris sold about $50,000 worth of bows this season, which is enough to equip 10,000 wagons. Speaking of the emigrating movement, caused by the drouth, Mr. Harris said that Arkansas and Texas have received many new settlers by it. The people of Texas have begun to realize that the best emigrants do not come from foreign countries, but from among dissatisfied citizens in the North and West. They have, consequently, turned their attention more to that class.—St. Louis Globe-Democrat.

TELEGRAPH LINES throughout the world aggregate 1,069,123 miles; of these America has more than half, 548,822 miles; Europe, 382,937; Asia, 67,875; Australasia, 47,812; and Africa, 21,687 miles.

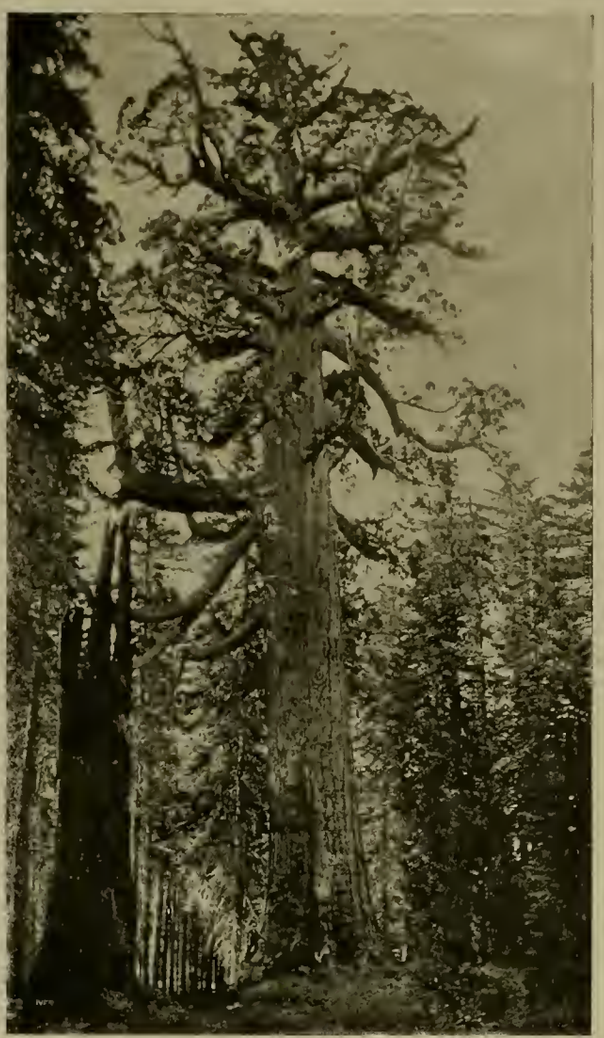
Specters of the Forest.

From the earliest written words the forest has furnished a symbolry for the various stages of human existence and for the various attributes thereof. The pliancy of youth, the exuberant strength of perfect maturity, the decay of age—all these and their innumerable accompaniments have suggested parallels between man and the tree. The greatest poets and the barbarous denizens of the untracked forest have risen together to the same height of imagery and the same tokens of emotion and sentiment. Evidently the tree appeals directly to the mind of man and conveys a lesson which needs no interpretation by culture or erudition.

The marks of age and approaching dissolution in the tree and in the man have perhaps been most widely noted. "I am like an old fir tree—dead at the top," said a decrepit chief of the Oneidas as he conversed with the pale face and showed his silvery locks. Hale old age has been brought to look upon the old monarch of the forest in these words: "His own bald head and grizzled locks—his own top with its decaying foliage—will make him feel a secret sympathy for some grizzled giant of the forest, old and decaying, but still strong and self-reliant."

Our engravings on this page suggest such thoughts as these. We have shown many trees in their prime and in their youth, but few in their old age and in the spectral form which some trees assume after the sap has ceased to flow and foliage no longer shields their stems from the bleaching sun. A dying *sequoia gigantea* is one of the themes of our engraver this week. It has reached its massive growth and its stature can be estimated by the pigmy-like men at its base. Death and decay have stricken it sorely. Storms have wrested from their places many of its spreading arms, and yet from the dying stumps there come a few foliage-bearing boughs to betoken its possession of life, even though strength and vigor have departed. Its majesty, even in death, over the full-grown and vigorous pines which surround it is but a symbol that some men, even in their death, are greater than the most vigorous humanity which bustles about during their declining years. Such have been some of the world's heroes—those in whom noble purpose has led to lofty thoughts and peerless deeds.

But there is a step beyond the symbolry of real life in the forest. The mystic and appalling are there as well, and how amid active life the specter stands both among men and among trees. Could there be a more forcible reminder of this fact than the ghostly form of a cypress of other days, which the engraving shows beside a roadway on Cypress point, in Monterey county? Very impressive are these bleached skeletons of the cypress. Gnarled and bent are they in old age, after a century perhaps of endurance of the ocean blasts upon a bleak promontory, but the strength gained by such knitting of fibers during decades of resistance will not permit them to seek rest prone along upon the welcoming breast of mother earth. Still must they stand, bleached by sun and beaten by rain and buffeted by winds, leading a spectral existence when the remains of other trees have silently sunken to rest and are indistinguishable in substance from the soil from which they sprang.



AN AGED SEQUOIA IN A PINE FOREST.

THE GHOST OF THE FOREST ON CYPRESS POINT.

According to the engineers of the Hydrographic Bureau, the level of the Gulf of Mexico is one foot higher than it was in 1859, and, of course, the encroachment on the surrounding coasts has been greater or less, depending on their character. In some places, where the marginal lands are composed of high, rocky bluffs, this change of level has gone on from year to year without attracting attention. On the other hand, many low-lying points (some that were once inhabited by the pioneer white settlers) are entirely submerged.

In a recent issue we commented upon the high price asked for platinum. An American technical journal takes us to task on this point, and although we do not see any reason to alter the opinion expressed, we are quite ready to listen to the other side of the question. It is stated that popular opinion concerning the great value of platinum is largely at fault. One frequently hears the statement that platinum is more valuable than gold. Nothing, we are informed, could be further from the truth. Pure platinum is worth about thirty-three shillings per ounce. Once, owing to the speculations of certain brokers, it reached a top figure of about sixty shillings per ounce, but soon fell back to the normal, and has in recent years been as low as twenty-five shillings. Pure gold all over the world has never been less than an average of four pounds per ounce. About three tons of platinum are annually consumed in America in the manufacture of incandescent lamps and for electrical purposes, while another ton is used for the more prosaic but no less useful purpose of being made into parts of artificial teeth.—Industries and Iron, London, Eng.

The latest dictionary contains 349,333 words. The old unabridged had only 125,000. Times are getting harder every year for the man who does not know how to spell, but life is getting easier all the time for the people who want to conceal their thoughts.

Senator Jones' Luck.

Major M. P. Handy, in the New York *Mail and Express*, gives a conversation with a Texas Congressman, who makes the following reference to John P. Jones: "Senator Jones," said the member from Texas, while he is a man of great native ability and has a mind enriched by reading, travel and experience, had his wealth come to him at first by a very slender chance. He was, by the way, although most people have forgotten it, the first of the multi-millionaires who came out of the Pacific coast mines to dazzle the East with their wealth. The first time he came to New York after making his great strike in the Crown Point mine, I came with him. We went to the Grand Opera House, on Twenty-third street, to see Charles Fletcher play 'Monte Cristo.' It was a great performance and impressed Senator Jones very much. When I commented upon the audacious improbability of the story of Edmund Dantes, he challenged the comment by the only reference to his own wealth which I ever heard him make.

"'Why,' said he, 'the story can be almost matched in my own career. Three years ago I was a miner with pick in hand and a Davy lamp on my hat, spending eighteen hours out of twenty-four in the bowels of the earth. Now I am a United States Senator and the owner of $10,000,000. Neither Dumas or the author of the Arabian Nights Entertainments could invent a story more wildly improbable to the commonplace imagination.'

"I asked the Senator then," continued the member from Texas, "the very question that we are considering—how much luck had to do with his amassing such a fortune?

"'I won't say everything,' was the reply, 'but you may judge for yourself how much when I tell you that if I had not taken a certain side of the street one day I probably would have been back at this moment on an Ohio farm tilling the soil with my own hands. It happened in this way: I had made some money during flush times in California, but struck a bad streak of luck and lost it all. Worse than that, I owed about $4000, without any prospect whatever of being able to pay. Being discouraged, I determined to go back to the States and try to make a quiet living in my old home. With that view I bought a ticket to New York by the Pacific Mail line and had actually gone aboard the vessel when I remembered that I had left some of my luggage at the hotel. I hurried back after it, and in doing so, by mere chance, perhaps because it was sunny on the other, took a side street upon which I had never walked before in my life. In my hurry I ran against an old friend, Alvinza Hayward by name. He asked me where I was going. I told him, and he begged me to reconsider. I was the very man he wanted to see. He wanted me to go and take the superintendence of a mine that he thought might have a good stake in it. He offered me a fair salary, which I accepted. I ran and got my things off the boat, and in a week was at work again in the mines. Before the year was out I was a millionaire. All the results of my forgetfulness in leaving a piece of baggage, and because I went up one side of the street instead of the other.'"

The gold-beating industry is threatened with extinction by the Swan process of preparing gold leaf. This consists of depositing a thin coating of gold upon a copper base, and then dissolving the base by submission to perchloride of iron. It is stated that the leaf may by this means be made of the thickness of $\frac{1}{4000000}$ of an inch. The copper being ultimately recoverable, the process is reported to be in every way economical, the reduction in weight in the leaf effecting a further saving of eighty per cent of the precious metal.

A London journal says that since the introduction of the electric light public performers are able to preserve their voices in better condition, and are fifty per cent more often in good voice. They are cooler, do not perspire, and are not husky while singing or acting. The atmosphere is better, and the equal temperature of the whole building has greatly diminished the risk of taking cold. Their throats are not parched and their voices not injured so much as in houses where gaslight is used.

The Executive and the Mining Bureau.

To the Editor:—Your able defense of the Mining Bureau, iu the attack upon it recently made iu the Legislaturc, enlists the sympathy and will receive the cordial support of the whole mining community of California. Periodical as these attacks bave been, and due to sectional prejudices aud the ignorance of the best interests of the State, the present attack appears in a different light and from a source least expected by the miners of California. Senator Langford's bill is but a uatural sequence of the utterauces contained in Governor Budd's inaugural address, in which his sweeping scheme of retrenchment and reform was promulgated, and its methods now become appareut in the effort to destroy the usefulness of the only State institutiou iu California conducted in thc interest of and for the benefit of our mining iudustry.

I sincerely hope that but few of our representatives will find, as Governor Budd fondly imagines, a panacea for present extravagance aud mismauagement in bis hobby to incorporate with the State University the most of our State commissions, societies and bureaus; but whatever policy may be found to defend such action, it cannot be said to exist in the case of the Mining Bureau.

Every citizen of California, familiar, like the writer, with this institution, from the time wheu Henry G. Hanks aud his solitary assistant struggled to obtain its recoguition until the present day, can trace its growth and development and bear testimony to its usefulness and freedom from the control of cliques and of the political machine. To-day we find its well-arranged but somewhat confined museum presenting to citizens aud strangers alike an epitome of the mineral wealth of our State; its small but useful library offers information to our miners; its laboratory gives its services to investigate our minerals; and its chief and his staff respond courteously to any reasonable demand of the public. A criticism of its activity can ouly find fault with a short period during Mr. Irelan's administration, when the redundancy of its reports in extraneous matter was justly objected to. With the means at its command, the last (twelfth) report may be said to be a model of its kind, and contains many valuable papers, such as "Electric Transmissions in Mining Operations" and "Auriferous Conglomerates of California," while its bulletins lately issued on "Mine Timbering," "Gas and Petroleum Formations" and "The Cyanide Process" furnish practical iuformation of the greatest value to the whole State. The reports of the Bureau are higbly valued by mining men all the world over, aud have been absorbed with avidity, so that the older issues cau scarcely be had at any price—a striking contrast to other reports issued by our State institutions.

During the present period of finaucial and industrial depression, when our mining industry is about the only one enjoying any prosperity and giving a fair promise of further and healthful expansion, due largely to the activity of the Bureau, it becomes not only injudicious but highly reprehensible to discard the services or decry the usefulness of a faithful and efficient State institutiou, on the score of a false economy which lavishes millions while it denies thousands. In so doing it is proposed to enter upon au experimeut tried time aud again in all civilized countries and always found wanting.

As Mr. Laugford's bill proposes to merge the Mining Bureau into the State University, it will not be out of place to review the history of that iustitutiou and its influcnce upon the mining industry of California, and in so doing the writer disclaims any hostility to the University and its faculty, whose scientific abilities and standing are well known aud ackuowledged by our citizens of all classes.

Founded in 1869, aud liberally endowed by the State aud the general Government, and constantly enlarged aud extended by liberal and seldom grudged appropriatious, it possesses all thc elements of large and extended usefulucss *within its particular domain*. At this session it is an applicant for appropriations aggregating $750,000, and so far our Executive bas not raised his voice against this expenditure. Its collections in natural history are large and constantly increasing, and comprise all the material collected by the State Geological Survey under Professor Whitney; its laboratories and worksbops are large and generally well supplied with tools and instruments; it bas its owu press, its experimental grounds, and its own football club. Contrasted with all this wealth of material, the resources of our Mining Bureau appear ridiculously small and insiguificant, even to its oldest friends.

Among its many and varied departments, the University maintaius a College of Miuing, in which Prof. Samuel B. Christy is an eminent and able instructor. This college has been in active operation for at least fifteen years, and its equipment will soon be complete, a full complement of milling machinery only being lacking.

The University issues from time to time bulletins of the special work doue by its faculty and its students, but no effort is made for their distribution, with the result that they are but little known to the press or the people of this State, no matter wbat their scope or importance may be. Every year the graduates of the University go forth into active life, well prepared for their duties, and to illustrate in their lives the teacbings, tbe precepts, the metbods and the spirit of progress that animates their "alma mater" in the quiet sbades of Berkeley.

With all this wealtb of expenditure, of preparation and of labor, what has been its influence intellectually, morally, and industrially, on the progress of this State during the twenty-five years of the life of the University?—and I pause bere to ask the members of our Legislature and our Executive that simple question.

In all that relates to Letters, Agriculture, Law, Medicine, and perhaps even to Chemistry, Mechanics and Engineering, I leave the answer to abler voices than my own. But in the department of Mining, a life work spent in the industry, may perhaps entitle the writer to form a fair judgment.

Underlying nearly all the practical operations of mining and milling as practiced in California, and governing or influencing their results, exist various physical forces but little known and quite obscure even to the average man of intelligence and education. Practical experiment will occasionally indicate the laws governing such forces and lead to economic success, but more frequently they remain unsolved enigmas, and the work done under such conditions is but a groping in the dark for approximate results.

The recognized improvements in the treatment of ores in California generally resolve themselves into perfected mechanical appliauces. As instances of but imperfectly understood metallurgical operations may be quoted: The amalgamation of gold and silver, the laws of which are as little known to-day as they were a hundred years ago; the laws governing wet and dry ore concentration; the chemistry of the application of chemical solvents to ores and ore products, especially in the cyanide process; and last, but uot least, the physical condition of our gold-bearing gravels. Confronted with such obscure questions in his daily work and not finding any information in standard works of science or aid from the teachings of our universities, the investigator pursues his way slowly and laboriously, chiefly for want of means, of instruments and apparatus, and perhaps spends half a lifetime to attain his object, if he succeeds at all. It is by emperical methods aloue that nearly all our mining and metallurgical operations have attained their present status, among which the economic application of the chlorination of gold ores may be mentioned and in which the names of Deetken and Theiss will always be remembered. It is true that honor is due to the work done by Prof. Christy in his researches on the volatility of gold in chlorinatiou, but the very methods of the University prevented for years this knowledge from bearing fruit, as it was not given to the public press directly, but just became known in the trausactions of the American Iustitute of Miniug Engineers—a record which, containing as it does the most valuable and important observations on subjects of mining engineering, cannot be said to be available for the general public.

An intimate knowledge of the condition and distribution of gold in our gravels, to be gained only by microscopical investigation, would, years ago, have modified the methods of hydraulic mining to such extent as to have prevented the injury to our valley lands; it would have saved more than one-half of the waste in gold now incidental to the method, and would have healed the distrust and the dissensions now so unfortunately preventing our farmers and miners from joining in mutual efforts for the common weal.

Our vast fields of placer miues yet remaining intact and generally overlooked by the professional geologist in his investigations in systematic geology, will yet tell a woudrous story of later geological eras when the evidences of our auriferous conglomerates, lately studied by Mr. R. L. Dunn for the Mining Bureau, have been interpreted and his deductions, as supported by the writer's experience, have been confirmed, in whicb case these formations would be analogous with the South African reefs in the Transvaal.

The writer will not attempt to define the scope of a State University or the duties of its faculty; its regents, if they represent the needs and aspirations of Californians, should determine these; but if such an institution, absorbing much of the wealth of the State, and ambitious of still greater power, should be more than a great high school, and should give part of its work to original scientific research and to the solution of important economic problems, the foregoing instances will serve to show but a few of the lines on which such research could be prosecuted for the advancement of mining and metallurgy in California. What, then, bas the State University done in these or kindred fields pertaining to its College of Mining?

To the reports of the United States Government; to the Geological Surveys, State and governmental; to the transactions of technical, engineering and scientific societies on this coast and elsewhere; to the Mining Bureau; to tireless, independent investigators; and to the untiring energy, industry and perseveranee of our mining men, do we owe what progress we have made in the mining industry, but not in any perceptible degree to the labors or the progressive spirit of our State University!

This lack of interest in tbe application of scientific research to practical industrial problems can hardly be blamed on the faculty of the University; it is more to be ascribed to the system, or to tbc general tendencies that apparently control nearly all the larger and wealthier American universities and colleges, which, once secure in wealth, influence and respectability, fall into the common rut of indolence and exclusiveness, and generally repudiate or fail to recognize merit in any original work done by investigators outside of their own collegiate limits.

But apart from this the University has its mission, distinct and divergent from that of a Mining Bureau, which, like our own, as defined under the Act of 1893, has its special province which the State University can never fill. The experience of older communities and nations in tbis respect is too well known to be disregarded, and is recommended to our Executive for his serious consideration. All the progressive nations of Europe, while possessiug or claiming the oldest, wealthiest and best equipped collegiate institutions of the world, have long ago severed the connection between their universities and tbcir mining schools, their technological institutes, their agricultural schools, and their museums and bureaus of applied science. Such is the case in England, France, Germany (famed for its universities as well as its mining schools), Belgium, Russia, Sweden and Norway. Such is also gencrally the practice in the eastern and middle States, where the most useful agricultural and technical schools have with manifest advantage been divorced from their colleges, and where more will follow, to meet the common sense demands of the American people.

It bas been left to the Governor of California to propose a retrograde movement and to attempt to sacrifice usefulness to prestige and privilege under the alluring watchword of retrenchment and reform, and in oblivion of the fundamental principles of true democracy; but the writer believes that the unbiascd common sense and justice of our legislators will prevent this injury to our mining iuterest, and instead of crippling the Mining Bureau or of allowing its absorption by our ambitious and powerfully supported University, they will provide more liberally than usual for our one popular institution, to the end that its usefulness may be exteuded and that the Mining Bureau may long remain as an aid and encouragement to that intrepid, patient and well-deserving part of our citizens—the California miners.

In conclusion, Mr. Editor, I would suggest that the Mining and Scientific Press should publish in an early issue, for public information, a comprehensive table of the endowments, incomes and appropriations in aid of the State University, from all sources, from its first foundation, and also its yearly expenditures, together with a full list of its ex-officio and appointed regents, who so far have withheld such information. In conjunction with this, the munificent appropriations for the Mining Bureau may be given as a parallel, so that the expenses incurred by the State for the so-called higher education may be contrasted by our economists with the sum allowed for the technical instruction of the common people.

J. A. Edman.

Meadow Valley, Cal., Feb. 14, 1895.

Reports of Two Experts.

Regarding the recent sale of the Poormau aud Tiger mines, P. C. Bunn, sent from London to examine the mines, says:

The Poorman and Tiger claims are both located upon the same fissure. The profits from the Poorman during the last five years have been $790,682. The Tiger mine, having been run by a private individual, it is impossible to get the gross production accurately, but for the present year, during which it has been worked 103 days, the net profit was $60,933. The railroad strikes and a serious washout of the railroad track prevented work being carried on for a longer period this year. The amalgamation of the properties would effect a great saving in the management and operating expenses. There is no douht hut that the mines can he worked to such depth as machinery can properly handle the product, and more than the present rate of production can be maintained for a great many years to come.

J. L. M. Fraser, the other expert from London, says:

The reserves of the Poorman mine above the ninth level are 135,700 tons; the stopes in these reserves produce 1590 tons of shipping ore per month. In the Tiger mine the eighth level is being driven in the rich shoot of ore which, for the first 115 feet, was ten feet wide—the present end is 30 feet—of ore; the stopes in these reserves produce 1282 tons of shipping ore per month. I value the plant and machinery at $516,000 (£104,000). By the amalgamation of the two mines I estimate a saving will he effected of $50,000 per annum, and a further saving by using the combined water powers. The output of the two mines should be 35,000 tons of shipping ore per year, which, at the present low prices, would produce a profit of $399,350 per year.

Colorado Mining Stocks.

COLORADO SPRINGS, COLO., Feb. 9, 1895.

Dissatisfaction and stagnation apparently reign supreme so far as mining stocks are concerned. Argentum-Juniata and Mollie Gibson appear to be entirely responsible. Rumored litigation emanating from the old Josephine company against the latter is having a depressing effect among a certain class. The authenticity of this it is impossible to trace. There are also rumors in circulation that the former company is liable to have trouble, to the effect that other parties have secured a patent upon a portion of territory supposed to be operated by the company. Both of these are absolutely rumors and can be taken for what they are worth, as it is exceedingly difficult to trace them to a reliable source.

I believe there will be an early reaction in silver stocks very shortly, although Mollie Gibson may be selling at nearly its market value. I truly believe Argentum-Juniata is a good purchase, as it is practically an unexplored virgin mine. But regardless of this, silver stocks are not in high favor, not excepting the Creedes which heretofore have been very strong, but they are now generally weakening, as the offered price of United Mines will attest. Happily, such stocks as Anaconda, Portland and Union are having a stimulating effect upon the market, which, in a way, has a tendency to overcome the injurious effect occasioned by silvers.

In order to insure permanency to mining stock speculation and retain public confidence, the management of companies must be more economical, honest and intelligent, and until such a state of affairs is effected, the business will be, as it now is, invariably looked upon with more or less distrust, and the experience of the ordinary outside investor can only be of a disastrous nature. In many organizations like Portland, Victor, Moose, Nugget and others, principally close corporations, there is evidence of reform, but unfortunately the outsider is either not attracted toward them, or given an opportunity to share in these mining plums. The avariciousness for quick returns, disinclination of brokers to recommend anything but listed stocks, is principally responsible for this.

The chief disadvantage of unlisted stocks is the difficulty of immediately realizing at a moment's notice without materially sacrificing them, but this is generally counteracted by the regular reception of dividends. If investors would give more attention to permanent investments and less consideration to what cannot be considered anything but petty gambling, they would soon look upon mining with more favor, and if brokers would carefully consider the possible result in legitimate mining and not give so much attention to stock manipulation, it would be better for all. Very respectfully,

F. H. PETTINGELL.

As Told by Judge Goodwin.

Judge Goodwin, who so ably fills the editorial chair of the Salt Lake *Tribune*, occasionally unbends to the extent of putting in articles not wholly statistic or didactic in his leaded columns. In the issue to hand he narrates the following:

A Nevada man once went to Europe to sell a mine. When he got his fare paid in New York he had the bond of the mine and $30 in his pocket. He found some soft Englishmen aboard who thought they could play poker. When he reached Liverpool he had the bond and $1200 in his pocket. He had not a vast amount of intellect, but he had an unlimited supply of that article called gall. In two months he had £8000 in the bank and had himself elected superintendent of the company in Nevada at a generous salary. He was feeling well. Going up street he saw some strawberries in a window. He did not remember that it was in the winter time, and that possibly strawberries were a little expensive, so he went in and ordered a plate of strawberries. The waiter stared at him and said: "I beg your pardon." "Don't you understand English?" asked the Nevada man, "I want a dish of strawberries." The waiter bowed and went out. Two English gentlemen were sitting at a table near by, and the Nevada man heard one of them say in a low tone to the other: "Upon my soul, I think when that Yank comes to pay for his strawberries he will never order any more in the Kingdom." The waiter brought a few sickly-looking berries, which were quickly disposed of, and then asked the amount of the bill. The waiter replied: "One guinea, if you please." "What!" said the Nevada man. "One guinea, if you please," answered the waiter. "Why, —— ——," said the Nevada man. "I thought strawberries were scarce and high. Bring me another plate." His gall still triumphed. When he returned he told the story, and a friend asked him if after he disposed of the second plate he ever did buy any more strawberries in the Kingdom. "Not a —— one," was the reply; "that last one was all for the American eagle."

"WHY does a bicycle stand up?" is a question which has been quite thoroughly discussed. But what the average amateur wants to know is, why a bicycle *doesn't* stand up.

Tried the Experiment.

In the winter of '93 4, and again in '94 5, it was suggested that relief could be afforded some of the indigent unemployed, who annually crowd into this city, if they were furnished with mining implements and sent to the foothills to try their luck at placer mining. The plan met with a good deal of well-grounded opposition, but one man, P. M. McFadden, prominent as an "organizer" of the unemployed, thought he would try the experiment. He claims to have made a success of it. Here is his alleged experience:

"I first went to Folsom and there got a little work on a gravel train. I saw hundreds of Chinese doing placer mining the old-fashioned way, and I followed their example. After five months' work I can say that it pays much better than cleaning the streets, and that there is room for thousands in this State to do this work. I located a claim on the Natoma grant, near Folsom. Five dollars bought me a rocker and pick and I rented the water privilege for $3 a month. I had never done mining before, but I made 60 cents a day from the start, and after a little advice from experts I readily earned $2 to $3 a day. Once I earned $50 in a few hours.

"The land around Folsom is owned by a large company, which allows mining on its ground and charges miners for use of water out of the ditch. My expenses were seldom over $2 a week, and one can fare very well at that—flour, bacon and potatoes, with a little fresh meat once or twice a week. There are plenty of empty cabins around that one can use, and no one will object.

"There are twenty men on the Natoma grant working just as I did, and all are making more than a living. There is room there for hundreds, and all over the State there are good placer districts where thousands of the unemployed can find work."

Structure of Gold Nuggets.

The structure of gold nuggets is the subject of a paper recently contributed to the New South Wales Royal Society by Professor Liverbridge. Gold nuggets, on being cut through, or sliced and polished, and then etched by chlorine water, were found to exhibit a well marked crystalline structure, closely resembling the figures shown by most metallic meteorites. On heating the nuggets in a Bunsen burner, blebs or blisters form, on both the polished and unpolished surfaces; and, on still more strongly heating, these, in some cases, burst with sharp reports, and pieces of gold are projected with considerable violence. As no explosions have been observed on dissolving or eating away the crusts of these blisters by chlorine water, it would appear that the blebs are probably due to the vaporization of some liquid or solid substance. As soon as a fresh supply of nuggets is obtained, experiments will be proceeded with to ascertain definitely whether gold nuggets contain occluded gases, or liquids, or solids which are vaporizable. In slicing some nuggets, scattered granules of quartz were met with inside, although quite invisible outside, and at first it was thought that the explosions might be due to the quartz, but the gas, in some cases, continued to issue from the burst bleb—where the aperture formed was small—and forced the Bunsen flame out into lateral jets, just as if urged by a blowpipe.

NOT many days ago, says the New York *Herald*, a few gentlemen connected with the telegraphic or electric business were assembled in a room in the eleventh story of the new Postal building on Broadway. They had not been there very long when astonishment was depicted on their faces; and by and by found expression in words. A book on the table about which they stood or sat was speaking. "Is it possible," exclaimed Mr. Chandler of the Commercial Cable Company, "that those spoken words can come from that book?" "Yes it is," said Mr. Francis W. Jones, the electrician of the company; "that is Mr. Marshall's telephone." W. Marshall, of 709 Lexington Ave., had prepared this remarkable feat for the electricians. He began by taking up an ordinary book and placing in the leaves several slips of tin foil, about one and a half inches wide and four inches long. Then he attached a couple of fine wires to another room, where they were attached to the transmitter of a telephone. Then a conversation began, with Mr. Marshall in one room, and one of the persons in the room where the book lay. Each word that came from the book could be distinctly heard in every corner of the room. The visitors had never experienced anything of the kind before, and they said it would eventually revolutionize telegraphy.

A PULSEOMETER has been invented with which it is claimed it is possible to tell to a fraction the exact condition of the heart beat. An electric pen traces on prepared paper the ongoings, haltings and peregrinations of the blood, showing with the fidelity of science the weakness of the telltale pulse. This should, it is considered, be of special advantage to life-insurance doctors, as well as to the profession at large.

To Save Fine Gold.

B. M. Whiting of Spokane, Wash., is making a machine for saving fine gold. The principal new feature is a revolving perforated cylinder, set at a slight inclination downward from the hopper. This is encased in a revolving drum and set in a box, equipped with riffles. There are two sets of copper plates and quicksilver riffles, and so constructed as never to clog. Within the drum and outside the cylinder are three copper balls, quicksilvered, kept in motion by the revolutions of the drum, and designed to pick up any straying particles of gold not caught in the other process. The dirt passes directly into the cylinder from the hopper, the water and all the fine substances passing through the perforations and not permitted to escape without coming into contact in passing over the system of plates. The gravel and all coarse stuff, after being thoroughly washed, is expelled at the end of the cylinder and sluiced out of the way. The weight of the drum and cylinder in the largest machine is about forty-five pounds.

This machine is designed to treat twenty-four yards of dirt in a day of ten hours. It requires fifteen inches of water, necessitating a six-inch pump at thirty-five revolutions a minute to raise the water ten feet, which is deemed sufficient on ordinary placer ground, as the height of the machine is only three feet. The machine itself is easily operated by hand, and the inventor claims that in actual service on the ground it will require less than a half-horse power, while the smaller sizes, intended for prospecting, can be worked by two men, one to shovel in the dirt and the other to turn the crank. It is so constructed that a cleanup can be made every day, or as often as desired.

If the machine performs as successfully in the field as it does on dress parade in the factory, it will largely revolutionize placer mining on the Columbia and tributary streams.

What Colorado Miners Want.

The Rocky Mountain *News* prints an open letter, which it states was signed by ninety-six working miners and addressed to the Tenth General Assembly of Colorado, in which they suggest amendments to the laws, as follows, so as to make:

1. Eight hours a legal day's work for all men working under ground.
2. Require all mines 100 or more feet deep to have at least two exits.
3. To forbid storage of powder or caps in or within fifty feet of shaft house.
4. To prohibit the employment of coolie labor in mines.
5. To require all incorporated companies to pay their laborers at least semi-monthly.
6. To compel all mining corporations offering stock for sale, or those whose stock is held by any person other than the directors of said company, to publish semi-annually, in some newspaper of general circulation in the county where they operate, a full statement showing assets and liabilities, income and expenditures, this statement to be signed under oath by at least two of the company's directors.

The Boot on the Other Leg.

California, Colorado and Montana all seem to be deriving benefit from the increased activity in gold mining, and our exchanges unanimously speak of the unusual amount of gold coming into the local mints. In the first-named State there is reported to be a very good and brisk demand for gold mining properties. People are commencing to have a fuller appreciation of the industry, and they are on the lookout for profitable investments. The San Francisco MINING AND SCIENTIFIC PRESS complains, however that "the only difficulty is these people want developed claims which are paying or about ready to pay, and these the miners want good prices for. A good many people in search of mines want developed ones at the price of prospects." In Australia the boot is on the other leg. Generally speaking, those who have mines to dispose of try—and in the case of West Australia have succeeded to a remarkable degree—to get for prospects the prices of developed properties.—Australia Mining Standard.

PHYSICAL DETERIORATION has been increasing steadily in the British army in the last twenty years. In 1875 there were only 65 soldiers in a thousand under five foot five; last year there were 127. The 608 in a thousand measuring less than 37 inches round the chest has grown to 685. The proportion of enlisted men under 20 years of age has increased from 97 in a thousand to 170, while that of men over 30 has decreased from 340 to 88 in a thousand.

THE Tacoma chamber of commerce has forwarded to Washington city a vigorous protest against the provision of the sundry civil bill by which a portion of the coast and geodetic survey force is to be dropped.

Scientific Progress.

Advice to Inventors.

Inventors may be roughly divided into three classes: (1) Those who, as the result of accident and momentary inspiration, think out one or two devices having no special relation to their ordinary pursuits or needs; (2) persons who have a well-defined mechanical genius, aud are regularly employed in some manufacturing trade, and a good deal giveu to the use of tools and the study of problems incidental to mechauics; and (3) experts in electricity, steam engineering, steel and irou works, or some other industry, who are constantly employed by some one else at a salary to improve existing methods and appliances. The first two of these classes, together constituting uinety-nine per cent of the whole, may be called, without disrespect or disparagement, amateur inventors. Those coustituting the third set are really "professional inventors." Some excellent suggestions, offered to the latter in the *Engineering Magazine* for February, by Henry Harrisou Suplee, deserve consideration by the former.

This writer's first recommendation is that when a man gets an idea he should go to work and find out what others have done in the same direction., so that he will not discover, after throwing away a lot of labor and time and perhaps money, that some one else has tried the same thing and succeeded, or has tried and failed. All failures should be carefully studied, so that the reasons therefor cau be detected and a repetition avoided. It is well to collect facts, either in the form of clippings or written memoranda, copies of pateuts or manufacturers' catalogues, about other devices like that which the inventor has in mind. Above all, it is important that a man, before trying to solve a problem, carefully inquire whether it is worth solving. Merchants, mauufacturers and consumers should be consulted to see whether a thiug would sell if perfected and put on the market. Finally, mechauical laws, means of accomplishing an end simply without waste of power or material and fuudamental principles should be eagerly and thoroughly studied in books, by personal observation aud by inquiry. It is the iuventor who works along these lines and looks upon invention as a science and not as a haphazard affair who makes the greatest hits commercially.

Freezing a Soap Bubble.

One of the most wouderful achievements in recent scientific progress is the liquefaction of air. A remarkable story of this curious substance and a soap bubble experiment is told in a late review of scientific experimeuts:

"A frozen soap bubble, broken in two, and floating like an iridesceut, transparent egg shell on the surface of a vessel of liquid air was one of the marvels exhibited by Professor Dewar iu a recent lecture before the Royal Iustitute of Great Britain. The lecture was on atmosphere and the curious effects of intense cold, the liquid air and the soap bubble being adjuncts introduced to facilitate some explauations. A few spoonfuls of the liquid air were poured into a vessel and the intense cold caused by evaporation immediately induced a miniature snowstorm in the atmosphere directly above the vessel.

"A soap bubble was then lowered into the freezing stratum above the liquid air. Almost instantly there was a change in the color of the transparent globe, the bubble becoming much darker; the movements of the rainbow film grew slower; it contracted somewhat in size and a moment later froze.

"A slight but dexterous movemeut of the rod upon which the bubble was suspended broke the latter in two pieces, which fell, cup side up, upon the liquid air and there floated for an hour, gradually accumulating a tiny snow drift from the almost imperceptible precipitation constantly going ou in the freezing atmosphere above."

THE astronomical observatory erected by Professor T. S. C. Lowe, is seven miles by rail north of Pasadena and sixteen miles northeast of Los Angeles. The Sierra Madre mountains, upon which the observatory has been placed, have an east and west trend, and rise abruptly from the San Gabriel valley on the south to an altitude exceeding 6000 feet above sea level. The observatory is built upon a southern spur of these mountains. Its altitude is about 3600 feet above the sea, and 2000 feet above the hills at the base of the mountains, which are very steep at this point. While the crest of the range rises high above the observatory and shelters it on the north, leaving, however, the north star visible, the entire southern horizon is uuobstructed, exteuding to the rim of a large segment of the ocean. Astronomically it is nearly at the intersection of the 34th parallel of north latitude with the 118th meridian of W. longitude. The new observatory is well equipped with the great sixteen-inch Clark reflector. Among the other instruments are many which have done notable work in the Warner observatory at Rochester under the directorship of Dr. Lewis Swift, the emiuent American astronomer, who uow superintends the Lowe observatory. The buildings consist of a central tower thirty-two feet in diameter, surrounded by a light dome, and two unequal wings, the smaller one contaiuing a dark room for photographic work, and the larger being furuished with cases for the extensive astronomical library of reference gathered by Dr. Swift in the course of his professioual career.

What a Cannon Ball Can Do.

In dwelling upon the wonderful power of the guns of the Indiana, Albert Frankliu Matthews, in an article on "The Evolution of a Battleship" iu the *Century*, gives illustratiou from the recent Chilean civil war, showing the effectiveness of the smaller sizes of brcechloading rifle guns.

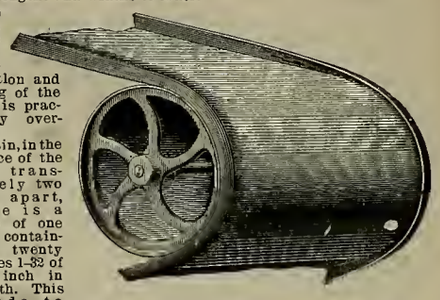
A shot weighing 250 pounds from an eight-inch gun of Fort Valdivavia, in Valparaiso harbor, struck the cruiser Blanco Encalada above the armor belt, passed through the thin steel plate on the side, went through the captain's cabin, took the pillow from under his head, dropped his head on the mattress with a thump but without injuring a hair, passed through the open door into the messroom, where it struck the floor and then glanced to the ceiling. Then it went through a wooden bulkhead an inch thick into a room twenty-five by forty-two feet, where forty meu were sleepiug iu hammocks. It killed six of them outright and wounded six others, three of whom died, after which it passed through a steel bulkhead five inches thick and ended its course by striking a battery outside, in which it made a dent nearly two inches deep. It was filled with sand. Had it released deadly gases no one knows what damage it might have done.

A 450-pound missile from a ten-inch gun in the same fort struck the same vessel on its eight-inch armor. It hit square on a bolt. The shell did uot pierce the armor but hurst outside the vessel. It drove the bolt clear through, and in its flight the bolt struck an eight inch gun, completely disabling it. Such is the power of the smaller sized guns.

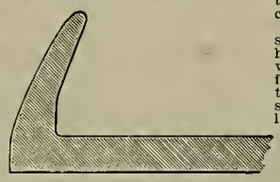
THE Turkish Ministry of Public Works has determined upon the reconstruction of the ancient water conduits of Jerusalem, dating from the age of King Solomou. By this means it would be possible to couvey 2500 cubic meters of water daily to the Holy City. Of this it is proposed to give 1000 meters away free of charge to the poor of Jerusalem, the distribution to take place at the Mosque of Omar, the Holy Sepulcher, and other places frequented by pilgrims. The new conduits are to be joined to the aucient aqueducts of Arob, and are to be carried through a tunnel 3570 yards iu length. The total outlay in connection with these works is estimated at 2,000,000 francs.

Blasdel Improved Concentrating Belt.

We keep in stock belts suitable for the Frue, Triumph, Johnston and Tullock machines, and make all lengths and widths to order.



Practical mill men must see at a glance the advantage of our belts over any other. First, the flanges stand at an acute angle toward the center, therefore readily conform to the change of direction while passing over the end rollers. Thus the vexation and loss occasioned by the frequent breaking of the flanges, as is the case with the old style, is practically overcome.



Again, in the surface of the belt transversely two feet apart, there is a space of one inch, containing twenty riffles 1-32 of an inch in depth. This tends to equalize the pulp and prevents it from banking on the edges, or forming channels. This riffle saves fine sulphurets and quicksilver that would escape with the tailings from a belt with an entirely smooth surface.

Mechanical Progress.

New Uses for Babbitt Metal.

I shall attempt in this article to give some of the numerous uses to which babbitt metal can be applied around the mill and workshop outside of its accustomed place in journal boxes. The writer of this was employed to fire a sawmill, and when I went and took charge of the machinery I noticed that the shaft of the rival pump that fed the boilers with water was sprung, caused by the plunger unscrewing from above, consequently lengthening it till it struck the bottom in running; the result was that when we started up, the wabble of the eccentric soon broke that rod in two. As it was thirty miles to a machine shop we were in a dilemma. I took the broken parts and shaft out and carried them to the proprietor and told him I would take them to the blacksmith's, and perhaps they could fix it. I also told him that if they could not, I thought I could make one out of babbitt metal. I took them to the shop and had the shaft straightened, but when they commenced work on the eccentric rod they broke it and it could not be repaired there. I then took the pieces with me and got a keyhole saw and made my molds out of wood. I then cast the broken parts out of the babbitt metal and got back to the mill in time to put them together and be ready for sawing the next day. I ran that mill two years, and that babbitt machinery was just as good when I quit as when I first put it on.

I do not advise the use of babbitt metal in every case, nor where a person is close to a machine shop, but in cases like the above where it would take a week or longer to get the repairs from the shop.

If you have a shaft to put up and have no cast bearings for it you can make them out of babbitt metal. I put up a two and one-quarter inch shaft and made the whole bearings out of babbitt metal. It has been running six years, and the bearings are apparently as good as when first made. I first made my bents and put them in place, having the top of the bents about one inch lower than the bottom of the shaft, when it was in place. I then put my shaft in place and got a cap block and cut a square notch in it about two inches larger than the diameter of the shaft. I placed this notch down over the shaft, the cap block resting on the bent with the shaft in the center of the notch. I then pinned the cap block solid to the bent, and bored a hole through the cap block to the notch to put a pin down against the shaft in order to have an oil hole when the box was run. We now fix the shaft in the center of the notch resting on outside supports. Get some good clay and pasteboard to fix the ends of the notch ready to run, leaving a place at the top to pour the metal. If you have been careful you will get a good boxing.

If your shafting is not perfectly round, it is best to tie one thickness of paper around the shaft and run the metal around that, turning the shaft a few rounds by hand, when the babbitt gets nearly cold.—H. N. Payton in the Tradesman.

Damascus Tempering.

A manuscript lately discovered gives in detail the method employed in making the famous Damascus blades. The manner of tempering is something almost too horrible to relate: "Let the high dignitary furnish an Ethiop of fair frame," the description runs, "and let him be bound down, shoulders upward, upon the block of the god Balhal, his arms fastened underneath with thongs; a strap of goat skin over his back and wound twice around the block; his feet close together, lashed to a dowel of wood, and his head and neck projecting over and beyond the block. Then let the master workman, having cold hammered the blade to a smooth and thin edge, thrust it into the fire of cedar wood coals, in and out, the while reciting the prayer to the god Bal-hal, until the steel be of the color of the red of the rising sun when he comes up over the desert toward the east; and then with a quick motion pass the same from the heel thereof to the point six times through the most fleshy portion of the slave's back and thighs, when it shall have become the color of the purple of the king. Then, if with one swing and one stroke of the right arm of the master workman it sever the head of the slave from his body and display not a nick nor crack along the edge, and the blade may be bent round about the body of a man and break not, it shall be accepted as a perfect weapon, sacred to the service of the god Balhal, and the owner thereof may thrust it into a scabbard of ass's skin, brazen with brass, and hung to a girdle of camel's wool dyed in the royal purple."—Blacksmith and Wheelwright.

Another Serious Blow to the Steam Engine.

With cruel "sarkazzum" the *American Machinist* says:

A number of imaginative persons are looking eagerly forward to the near future when, it is asserted, a certain vibrating device is to thrust aside our old and reliable friend, the steam engine, as a general agent for the development of power.

The invention, which, to quote the bulletins, "consists of the core of a steam engine and the core of a dynamo," is to develop far greater power per pound of fuel than even the best of our present engines, and is to save thirty-five per cent in initial mechanical friction, fifteen per cent in outside connection losses, and where electricity is to be produced, an added trifle of ten per cent for conversion, or a total of not less than sixty per cent over present practice.

Last, but not least, the improved motor is to occupy but a trifling space, the machine for a fair sized ocean steamer being stowable within an ordinary silk hat of the dimensions worn by, say, one of our vindicated police justices; and such being the case, the regular greyhounds can carry power enough to make the ocean passage in a couple of days at most.

Just what connection is to be made between the vibrator and the screw, or other shafting, does not appear.

Possibly it is considered that such a trifling problem requires no particular consideration from those who soar above the clouds in scientific contemplation, and who usually leave the unpoetic practical designer to wrestle alone with the questions that arise in forcing the coarse materials of nature to conform to the requirements of geniustic theory.

It is hardly probable that the new device will very greatly interfere with the coming spring trade in the regular type of steam machinery.

"Among the November boiler explosions," says the *Locomotive*, "we note one that is particularly distressing. The gentleman owning the plant, whom we will call Mr. Brown, had been repeatedly solicited to insure his boiler, but had steadily declined to do so. He had a good engineer, he said, and a good boiler, and he didn't need insurance. Once, when our agent visited him, he was a little petulant, and his conversation was, perhaps, more emphatic than polite. But within a week from that day his boiler blew up and destroyed the entire plant. He felt differently about the insurance after that; but when he had rebuilt his mill and saw everything running in good shape once more, he changed his mind again and said 'Lightning never strikes twice in the same place.' Last month the new boiler exploded, with disastrous results, and Mr. Brown was himself among the killed."

At the time the Pennsylvania company placed its recent 30,000-ton order for steel rails, at $22, it was believed that the lowest possible figure was reached, and that the mills would lose money on the contract. The *Wall Street News*, however, has found "one of the most prominent iron workers of Pittsburg," who says that the mills could have taken the order at $20, and made money on it. In the interview, the gentleman said: "Present prices will rule until July, I think, unless Tom Johnson completes his plant at Lorain, Ohio, and jumps into the market. He will pull rails down to $18. We have been doing a great deal of work for him, and his place is nearly done. He will have a magnificent plant—one of the largest in the country."

Earnings of Labor in 1890.

Some idea of the enormous interest of laborers and mechanics in this country's commerce is shown by the remarks of the Governor of Ohio, at the recent meeting of the National Association of Manufacturers in Cincinnati. "Do you know the amount of wages paid to the labor of this country in 1890 (the last census year)?" said Mr. McKinley. "The stupendous sum of $1,221,170,454, or $3,914,000 to each working day, or $391,400 for every working hour of every working day in that busy year.

"As showing the advance of our manufactures, we had exactly 950,000 more persons employed in the year 1890 than in 1880, and more in 1892 than in either period, and the aggregate of wages of 1892 was more than double the amount paid in 1880. No people of any other country ever had so large a share in so great a product as the working people of the United States then enjoyed. The value of the product of our manufactures in 1890 was more than 100 per cent greater than those of 1890. When the manufacturers in 1890 were prosperous the wage earners were equally prosperous; agriculture was profitable; railroads were actively employed, and merchants were doing a satisfactory business. Why, in 1891, the amount of the deposits in the savings banks of the country was $1,623,079,749, and it is estimated that ninety per cent of these deposits were the earnings of our wage earners received from our home manufacturers."

Practical Hydraulics.
A Book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers and Irrigators.
BY P. M. RANDALL.
This new work is by one of the most experienced hydraulicians of the country. It abounds with useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulæ, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules and tables are prepared. Thus the needs of the scientist and the practical miner or millman are each met. It is the most complete work on the subject yet published, and is specially applicable to the Pacific Coast.
TABLE OF CONTENTS.
The following brief abstract of the contents will give an idea of the branches of the subject treated:
General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulæ Obtained; Examples and Calculations; Extensive Tables for Ready Reference; Fundamental Laws of Hydraulics Demonstrated and Expressed in Formulæ and Rules; Flow of Water Through Openings; Weir Coefficients; Triangular Weirs; Flow of Water over Quadrant Weir (tabulated); Application of Tables; Submerged Orifices; Flow Through Orifices in Thin Partitions; Tables and Applications; Miners' Inches; Tables and Calculations; Flow of Water Through Short Tubes and Compound Tubes; Flow of Water Through Pipes; Tables of Velocities and Cubic Feet Flows for Given Fall per Mile and Diameter of Pipe; Coefficient for Bend—Circular and Angular; Flow Through Nozzles; Inverted Siphons; Flow of Water in Open Channels. Extensive Tables; Rough and Ready Notes; Hints for Speedy and Approximate Estimates, etc.
Price $2.00, postpaid. Sold by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

CHICAGO GOLD MINING SYNDICATE.—*Republican:* At the old Bunker Hill and Original Amador claims, near Amador City, operated by the Chicago Gold Miniug Syndicate, the wages aud other liabilities have got ahead of the premises. It has heen arranged that the proceeds of the mines, as well as the remittances from the East, should he divided pro rata among all the creditors. Under this arrangement, the work is now proceeding.

THE BEN HUR.—Hydraulicking at the Ben Hur placer claim at Pine Grove is in full blast. This was formerly known as the Wheeler claim, and, according to all accounts, it promises to have a long aud prosperous run. The auriferous ground is sufficient to last for many years.

ANITA.—At this mine sinking is progressing at a satisfactory rate. Last week they put in four sets of timbers, lowering the shaft 20 feet. The formation is slate, near the footwall, and is excellent working ground. The new hoisting works ruu smoothly. The shaft is now 120 feet deep. The water is troublesome, especially since the heavy rains of the past few days; hut the machinery is ahle to handle it without seriously interferiug with the sinking.

THE MEDIAN MINE.—*Record:* At the Mediau mine, Johu R. Tregloan, superintendent, a tramway is just finished which takes the ore from that miue to the mill of the South Spring Hill mine. Heretofore it cost the company ahout 80 ceuts per ton to get the ore to the mill. With the fiuishing of the new tramway the cost is less than eight cents per ton.

DRYTOWN DISTRICT.

THE GOVER.—*Ledger:* The lieu holders' cases against the Gover Mining Company have heen continued to March 4th. W. J. McGee, attorney for the company, says that negotiatious are still pending for the sale of the property, and if the sale can be affected, all the creditors will he paid in full. Jasper McDonald of the Keystone Company is still keepiug the water out of the Gover under his option of purchase, which has not yet expired.

JACKSON DISTRICT.

THE ZEILA.—The Zeila chlorination works have heen running ever since the mine and mill shut down on sulphurets on haud, hut the supply has all heen chlorinated and the works have shut down until the mill is again running.

Calaveras.

THE HEXTER MINE SOLD.—*Chronicle:* The Hexter mine, situated half-way hetween Mokelumne Hill and Middle Bar, has heen sold to Col. W. T. Rohinson, who has already commenced the work of prospecting for an ore body. Some thirty years ago this property was worked with a five-stamp mill. Exceedingly rich quartz was taken from the mine, hut, for causes unknown, the mill was removed from the miue, and for many years the property has heen idle. It is the opinion of Col. Robinson, who has carefully examined the property, that the original owners went through the apex of the ore shoot and then drifted the opposite way from the pay ore, and not finding any more good quartz they supposed the mine was played out. This is only one of many paying mines that were ahandoued hy mine operators thirty years ago, suhsequently to he opened and made to pay divideuds. The Kennedy mine of Jacksou and many others could he cited to hack up this statement.

The Hexter miue is situated hetween Mokelumne and Campo Seco canal, aud water under a 200-foot pressure can he had for the purpose of running all machinery necessary for cheap and economical working. The couuty road passes over the lode, so it is at once accessihle for large teams. The formation is porphyry on the hanging-wall and diahase and greenstone on the footwall. The fissure is five feet wide and chiefly filled with quartz carrying a small per cent of sulphurets and a record of $20 per ton in free gold. It is to he hoped that the future workings may develop a paying property, aud once more demonstrate to the miner of to-day that old ahandoned mines are worthy of his investigation.

CHANGED HANDS.—*Chronicle:* The Birney miue has virtually heen sold to Colonel Woodrow and other capitalists of Salt Lake City. Colonel Woodrow is uow en route to the Mormon city, and as soon as he arrives there he will probahly forward the money for the first payment, although he has until the 1st of April in which to do this. The deed to the property has heen made out and placed in escrow with Wells, Fargo & Co. until such a time as the second payment is made, the purchasers having six months from the 1st of April in which to make it.

The principal creditors of the Biruey Compauy held a meeting Wednesday evening and agreed to accept one-third of their claims when Col. Woodrow makes the first payment, and the halance when the second paymeut is made. The Colonel will reach his destination on the 21st inst., and expects to forward the money immediately. He is a wealthy mining expert and there is no douht ahout his sincerity in the matter. Like all others who have examined the Birney, he considers it a very valuahle property. His personal representative, Mr. McCreight, remained here to take charge of the property as soon as the first installment arrives.

The negotiations for the sale were conducted hy W. H. Routledge, who had an option on the property, on hehalf of the Birney Company, and J. T. Wall and Mr. McCreight on behalf of the Salt Lake City men. The transfer of the mine will prove heneficial to Angels, as it will he developed on an extensive scale and there will he ample means with which to prosecute the work.

The Missouri mine at Carson Hill has also heen sold to the Salt Lake City parties for $10,000, the payments to he made on the same hasis as those for the Birney. The property helonged to Joseph Peirano and Domingo Rolleri.

We uuderstand that Mr. Routledge has a hond on the Raspherry property and is negotiating for its sale.

Reports come to us of improvements heing made in the mill at the Mosser mine, near Mokelumne Hill, and also of the huilding of new hoisting works on the shaft. People residing in that locality have great faith in the future of the Mosser mine. It is a continuation of the old Lamphere lead.

THE BOSTON MINE.—*Chronicle:* The Boston mine, situated near Mokelumne Hill, and owned hy Louis Davidson & Co., will shortly he re-opened.

Del Norte.

AN OFFER REFUSED.—*Record:* Work on the ditch heing huilt hy the Del Norte Mining, Milling and Irrigation Company in the Big Flat country is progressiug rapidly. It is now thought hy those interested that the water can he hrought on the claims at an expense considerahly less thau was first estimated. The company has received an offer of $3000 for their property, from a Chicago man, which they refused. The memhers of the company will develop the mines themselves, and helieve when water is put on the claim they will have a honanza.

El Dorado.

GRAND VICTORY MINE. — *Republican:* The Grand Victory mine is the scene of active operatious at present. The mill is heing enlarged to a capacity of fifty stamps, and three rock hreakers are at work reducing ore from the mine to a size adapted for work hy the stamps. It is said that a recent discovery has heen made of ore mueh hetter than any hitherto worked.

Inyo.

MARBLE QUARRY. — C. B. Derhy is uow superintendent of the Inyo marhle quarry. The *Index* says the shipmeut of marhle will soon he resumed, and a numher of additional men have heeu put to work.

Mariposa.

GENERAL MINING NOTES.—*Gazette:* The mau who recently bonded the Daisy, Juhilee and Steveson quartz mine north of the river, has men at work, aud from the Daisy aud Juhilee comes news of the finding of an exceptionally rich hody of gold ore in each.

The work of the Sierra-Butte compauy at the Whitlock mine is progressing favorahly. The fine three-compartment shaft is now down over two hundred feet, and seventy-five men are employed in and arouud the mine. The first consignment of machinery for the 50-stamp mill arrived this week and is heing placed in positiou. The carpenter work on the mill and other huildings is heing forwarded as fast as circumstances will permit.

Several loads of mining supplies, track iron, ore cars, pipe, tools, etc., for the Heaton mine in Devil's Gulch, have heen sent up this week. Mr. Chapman has a uumher of men at work and is pushing things.

The grant people have the tunnels and drifts on the Pine Tree mine nearly all cleaned out, and now have a similar work in view on the Princeton mine, hoth old-time honanza properties.

Mono.

A REPORTED STRIKE.—It is reported that a strike has heen made in the Standard mine at Bodie, Cal., running through the Jupiter into Bodie ground, says the Virginia City *Enterprise.*

Nevada.

MINE BONDED.—*Tidings:* Prof. Geo. A. Treadwell has taken a hond on the Fountain Head gravel mine, in this district, and will endeavor to raise a working capital in England for the exploitatiou of the property. He will form an English company and raise sufficient working capital, in the heginning, to fully develop the claim, so that the stock will he unassessahle. This is in accordance with English law, as in that country assessments cannot he levied upon the stock of a corporation.

WILLOW VALLEY DISTRICT.

Herald: Considerahle prospecting is heing done. Several claims have heen honded and leased, and companies are heing organized to work them.

The Alice Belle, at which the Murchie company is doing its principal work, is progressing rapidly and giving up good ore.

The company now works three shifts in the old Murchie drain tunnel. The little four-stamp mill has plenty of rock to work on now.

At the Belle Fontaine work goes steadily on, and the ore taken out is high grade.

The Federal Loan is said to he in excellent ore still. It was, no douht, the success of the Federal Loan that stimulated mining in that district.

NEW MINING COMPANY.—The Cadmus Mining Company is soon to he incorporated, and will immediately commence the erection of hoisting works and hegin developing the claim. This is the McHugh location, adjoining the Home and Providence on the west. Charles Kaehle, formerly a foreman at the Providence, is to he superintendent.

Shasta.

TROUBLE AT QUARTZ HILL.—*Free Press:* The Kosciusco mine, at Quartz hill, is owned hy a Polish company, and the stockholders or directors are having trouhle among themselves. The company has expended ahout $90,000 on the mine so far and the ore has paid fairly well hy the common mill process. No douht, however, a percentage, and perhaps a large percentage, of the gold has escaped. Anyhow, from this or some other eause, there has heen and is trouhle. Recently a Polish priest and the secretary of the company arrived from the East, and there is an effort heing made to patch up a peace.

A GROWING DEMAND.—Redding *Free Press:* There seems to he a growing demand in Shasta county for mining properties, which ought certainly he encouraging to our poor mine owners, and spur them on in the development of their miues. Show the capitalist that you have something to sell, and there will he little trouhle in disposing of your property. The recent sale of the Iron Mountain mine for $300,000 will increase the demand for development properties.

San Diego.

BANNER DISTRICT.

NEW GOLD DISCOVERY.—A new gold discovery is reported east of Banner. The ore shows free gold and prospects well. Bacon & Coffman's mine is reported very rich, and the ledge maintains its width as the shaft is pushed down.

Sierra.

DANGEROUS AT PRESENT. — *Messenger:* The contractors who are running the tunnel at the Slug Canyon mine have heen unable to work the most of the week. Slug canyon is one solid mass of snow slides and it is dangerous for men to go up to the mine.

Placer.

THE GEM MINE.—*Sentinel:* Work at the Gem mine at Humhug is heiug pushed. The lower tunnel is iu ahout 200 feet and the upper tuunel not quite that distance. The miue is excellently situated for the huilding of a mill; and if the ledge proves to he what is expected from previous prospectiug, a large mill will go up ou the site. The ledge is only a few miles from the famous Pioneer, which is paying hetter now than at any time previously.

Tuolumne.

THE GOLDEN RULE.—*Independent:* On Tuesday, two-thirds of the Goldeu Rule quartz mine was sold to a San Francisco syndicate, hy the owner, Mr. McGinn—Mr. O. S. Cressy retaining the other third of the claim. The whole property heing valued at $100,000, the two-thirds was sold at that rate of valuation. The Golden Rule is located ahout one mile south of Quartz Mountain, and hids fair to hecome one of the most noted in Tuolumne.

NEVADA.

Storey.

THE COMSTOCK MINES.—At present, says Dan De Quille, most of the ore that is heing milled hy the Con. Cal. & Virginia Company is heing taken from the new hody of ore recently discovered to the southward on the 1650 level. Though this is good milling ore, it is not so rich as that in the main chimney through which the incline was sunk. During the past week the mill worked 175 tons of the new ore, the yield of which was $37.60 a ton. Thus it will he seen that the new hody was not a had find. In the new deposit an opening has heen made that is now fifteen feet loug and twelve feet wide.

The Hale & Norcross is yielding some ore, hut most of the work is exploratory. On the 975 level a small streak of oro was passed through in a crosscut, from which were taken six cars of ore that averaged $47.88 a ton. This is a very promising prospect.

The Alta is hecoming a steady producer. The yield last week was 124 cars of ore, worth $43.28 a ton.

The Crown Point is yielding nearly 600 tons a week of gold quartz, which averages over $9 a ton.

Both the Belcher and the Seg. Belcher are now heginning to yield small lots of fair-grade ore, which is quite encouraging.

The Potosi, Chollar and Occidental are yielding ahout as usual.

To the west of the main line of the croppings of the Comstock lode lies a region that is unexplored. Though immense sums have heen expended in prospecting to the north and south along the course of the Comstock, no work worthy of the name has ever heen done to the westward. Many large veins crop out in the unexplored western country, most of which yield good prospects in gold, hut on none of these has anything hut surface scratching heen done. It seems strange that this promising section should have heen allowed to lie unprospected for over thirty-five years, yet such is the fact. All the time, too, our oldest and hest miners have thought well of this region, hut the majority have heen afraid of the water it is supposed to contain. It is supposed that a great hody of water is held hack hehind the footwall of the Comstock lode. Some accidental tappings indicate that this is probahly the case, hut any water found would now he easily disposed of hy sending it out through the Sutro drain tunnel.

In this way the west country could he cheaply drained to the depth of over 1600 feet. At last one company is pushing out into this undeveloped seetion. This is the West Con. Virginia & California Company. They are running west from the 1100 level of the honanza mines, and, after passing through much hard and solid rock in the footwall of the Comstock lode, seem to he entering the confines of the west country. They have tapped quite a heavy flow of hot water, which shows a change of formation uear at hand. The hot water at the face of the drift caused a suspension of work, hut the flow is gradually decreasing. As the flow diminishes the water hecomes cooler, and soon work may he resumed in the drift. It is thought that some development of interest will soon he made in this drift. It is the first venture at depth into the west country, and hy means of it a discovery may he made that will give the Comstock a new lease of life, if not a rousing hoom. The hot water is a sure sign of ore, or at least vein material, somewhere ahead.

Lyon.

SILVER CITY NOTES.—*Times:* A. A. Pollard is having a new flume huilt from his reservoir in American canyon to the Pollard mill.

Everyhody is working—some on leases and some ou their own claims—and all are meeting with suceess.

All of the old mines are looking well, particularly the Oest, Haywood, Great Western, Succor, Overland and Brodek.

There are three mills now running—the Pollard, Foot and French. The others will start up very soou if good weather continues.

There is a large amount of ore out at the different dumps awaitiug hauling to the mills. It will he hauled as soon as the roads are in a condition for teams to move.

MILL FOR PINE NUT.—Genoa *Courier:* The San Francisco parties who hecame interested in the Zirn & Schultz claims will hegin the erection of a mill on or hefore the 1st of May, and have agreed to have it completed and running hy the 1st of August. The mill is to he of sufficient capacity to crush from twenty to forty tons a day, according to the character of the rock. These parties have also agreed to procure a supply of water for the camp. The water will have to he piped a distance of five miles. The total outlay for these improvements, it is estimated, will be not less than $10,000.

ARIZONA.

THE VULTURE TAILINGS. — *Courier:* The Helm Bros., now operating on the old Vulture tailings, are completing the erection of cyanide tanks, which process, it is said, is perfectly adapted to successfully handle this product. There are many huudreds of tons of these tailings which have lain idle for over twenty-five years; and, strange as it may appear, no interest was taken in the reducing them to metal until these mining men commenced to determine their real value. These tailings will run ahout $15 per ton; and from the cheapness of the method adopted to handle them, a fortune will he made hy it, so many miners say who have recently heen there.

GOLDFIELD NOTES.—Phœnix *Herald:* At the Mammoth mine, no ore is heing taken out at present. The main shaft has heen sunk 350 feet, at which point drifts are heing run to tap the veiu. Everything is in readiness, and it is said active operations will he resumed soon, and ore will he takeu out and the mill started up.

Some new and exceedingly rich ore has been struck on the Bull Dog property, which is heing thoroughly developed. The Pomeroy mill is workiug steadily on the 150 tons of ore from this property, and the plates show that the ore will average at least $25 per ton. This property is owned hy Phœnix people, who have already expended about $12,000 and who now see their way clear to a good-sized fortune.

The Fairstake and Sunset properties are heing worked and show up finely. A sensational story is promised regarding these claims in the near future.

H. J. Allen, of Jerome, said the report of the recent cave in the United Verde Copper Co.'s mines was a most cavernous fahrication, or words to that effect.

IN COPPER BASIN. — Tombstone *Epitaph:* Four men with two teams are at work in Copper Basin ground sluicing, and are said to be taking out $10 each per day of clean-looking gold dust. Another man was seen at work in the same locality with a rocker. He stated that he was making a good liviug.

BRITISH COLUMBIA.

QUARRIED OUT.—*Midway Advance:* A visitor to Fairview at the present time can see one of the greatest "snaps" in quartz mining to be seen anywhere. The quartz is heing literally quarried out hy four men, who manage to keep the ten-stamp mill supplied with ore.

COLORADO.

SOME COLORADO PRODUCERS.—*Ores and Metals:* The Golden Wedge, near Central, returned on 1,709 pounds of first class ore, 34.69 ozs. gold, 16.4 ozs. silver, and 15 per cent copper per ton, total commercial value $668.68. 4,675 pounds of second class ore gave 6.40 ozs. gold, 6 1-5 ozs. silver, and 7¼ per cent copper per ton, value $117.84 per ton.

The Mollie Gihson, the world's famous silver producer, will pay no dividend this month. Last month's receipts were only $20,000, barely enough to pay expenses. The mine is now in 40-ounce ore, which is a very low grade for the Mollie, hut it is confidently expected that rich ore will he found again soon.

The North Star mine on Sultan Mountain, Col., has an almost phenomenal record in that it has not heen shut down a day in eleven years. During that time it has shipped 25,000 tons of ore, and 5,000 tons of concentrates, which produced 2,000,000 ounces of silver, 108,000 ounces of gold, and 8,000 tons of lead. The average value of the ore in gold, silver, lead and copper is $62 a ton.

The Star mine at Ward, equipped ouly with rattletrap machinery, with not a drift helow 300 feet, is shipping daily a carload of ore worth $2,000. The Giles, another mine, keeps every availahle stamp in town steadily pounding; the Utica has 16 feet of ore running into the hundreds; the Modoc and Humholdt are each pounding out 50 tons a day, with good returns, while the great Columhia out-cripples Cripple Creek, with its daily output reaching toward $2,000—$60,000 a month. But they say there's a bigger mine thau this near Ward—the Dew Drop, over in California gulch. The operators of the Columhia say it themselves and they are in position to know.

Custer Co.

THE GEYSER MINE.—*Silver Cliff Rustler:* The Geyser mine is hetter than ever. A new mineral known as prousite has heen fouud. It is a crystallized ruhy silver and assays 16,000 ounces silver per tou. Late assays have shown as much as $86 in gold, and 21 assays made from the 2,100-foot level gave an average of 4,500 ounces in silver.

Mineral Co.

IN CREEDE DIST.—*Creede Candle:* At least 800 men are employed in and ahout the mines in this district. The pay roll for the last month is the largest since the slump in silver, and the force on several properties is con

stantly being increased. With the opening of spring at least 1,000 men will find employment in and around Creede camp.

IDAHO.

SOLD FOR $30,000.—The Salmon City *Recorder* learns that the Hughes Creek placer property, near Gibbonsville, has been sold to St. Paul capitalists for $30,000, a small sum being paid now and the balance to be made in regular payments within a year. This property was owned by Messrs. Fahey, Huat, Stein and others of Gibbonsville.

THE TIP-TOP.—Silver City *Avalanche:* The mill has started up again with forty stamps, and will be run steadily on half time (twelve hours). Forty tons per day can be treated in this manner, and it is impossible to keep ore at the mill when running its full capacity. Shelton & Eastwood, ore haulers, have about two hundred tons at the mill, and are hauling steadily with five teams.

World: Superintendent Wood of the Cumas No. 2 mine and mill came to town to-day bringing a gold brick that weighed exactly seventeen and a half pounds. At $16 per ounce troy the brick is worth about $4,000. This was the result of 15 days' run of 15 stamps.

Another brick worth about $1,500 having been brought in a couple of weeks ago, this makes about $5,500 worth of bullion brought in. A clean-up is now going on at the mill, which will doubtless result in $1,500 worth of gold additional.

In addition to the gold 60 tons of concentrates have been shipped since the mill started up. These are worth $80 per ton, and amount to $4,800.

We thus have a total of about $12,000 for about 25 days' run of 15 stamps.

Mr. Wood says that during that time he ran 500 tons of ore through the mill.

His expenses average $100 per day.

He expects to do much better the current month than he did last, especially as he will run 20 stamps instead of 15.

FAVORABLE INDICATIONS.—Weiser *Signal:* The prospects are that mining operations in Warrens the coming season will be more extensive than for many years. The number of heavy mining operators who are turning their attention to the camp bespeaks a leading position in the mining world. This is well for Warrens and well for Weiser.

LOWER CALIFORNIA.

AN AWAKENING.—*Lower Californian:* The revival of mining interests in California and the renewed impetus in that great industry, which for years has been sadly neglected, is already having its effect upon Lower California. Mining men are again awakening to the fact that there are rich mineral deposits throughout the length and breadth of this great peninsula, much of which is even unexplored. The prosperous condition of the Iharra Mining Company at Calmihi is apparent, and they are now employing some 300 men and expanding their facilities with improved machinery. In this section several mines are in profitable operation, and everything indicates a revival in mining interests. That the gold is here is self-evident, and pluck and capital are only necessary to open up many mines now lying idle and to put them on a good paying basis.

CEDROS ISLAND MINES.—H. A. Howard, representing Eastern capitalists, on the 5th inst. purchased a controlling interest of fifty-one shares in the Cedros Island Mining and Milling Company, and was installed again as general manager of the company. Mr. Howard says the deal means the immediate reopening of the work on the mines and the shipment of ore. During his management of the properties some years ago, the mines yielded a large amount of ore, much of which was handled through the port of San Diego. The new investors are also interested in Mr. Howard's gold mines at Jacalitos, on the peninsula, and machinery will be shipped there for development of the prospects.

MONTANA.

SEEKING INVESTMENT AND OCCUPATION.—Butte *Mining Review:* There are many strangers in town—mining experts, mill men, contractors, miners and speculators—all of whom are actively seeking investment or occupation in their various lines. The mines about here are improving and the mineral output increasing, and the time is shortcoming when mining matters will be pushed forward with vigor.

NEW MEXICO.

Grant Co.

WHITE SIGNAL.—*Enterprise:* The new strike in this district is a porphyritic-syenitic ledge, varying from five to seven feet in width, and, it is claimed, assays ranging from $5 to $45 per ton have been obtained.

This comparatively new gold mining district began its production and shipment of gold ore less than a year ago. To-day a fifty-ton mill is in course of erection, and will be in operation within forty days. John Brockman and company are putting in a Jannisch mill which will crush fifty tons of ore per day. The company have purchased several mines and have sufficient ore exposed on their own ground to keep the mill running.

PINOS ALTOS.—Spiller and McLean are working eighteen men on the Pacific Gold Company's claim, the Pacific. The ore is hauled to the company's mill, north of Silver City, for reduction.

OREGON.

THE ASHLAND MINE.—*Tidings:* The miners and other creditors of the Ashland mine, which has not been managed to suit many of them for some time past, have been in Ashland consulting, and it is understood that a number of additional liens against the property will be filed at once and Judge Hanna petitioned to appoint a receiver for the property. The mine is advertised to be sold upon execution on the 23d, but it is not likely that the sale will take place. The mine was never in a more promising condition, it is said, as far as showing up good paying rock is concerned.

Jackson Co.

The San Francisco parties who had the Mountain Lion mine, on Missouri flat, bonded, have given it up and Bailey Bros. are again in possession.

The Hammersly mine is gradually bringing its owners out of deep water. The mine has already cleared off some $13,000 indebtedness, and is only partly opened as yet.

Jeanie Bros., who have purchased the placer claims of Keuney, Bonson and Anderson, on Sardine creek, have put in two giants with eleven-inch pipe, and expect to make a good showing during the season.

UTAH.

ANOTHER GOLD MINE.—The Bullion-Beck places itself on record as a gold mine, a rich strike having just been made on the 700-foot level. It is the first time gold in paying quantities has been discovered in the Beck, all of the previous assays showing simply traces of the yellow metal. The body of ore just uncovered shows average returns of $40 in gold, over 100 ounces of silver and the usual amount of lead and copper. Members of the directory report it as making a splendid showing and increasing in magnitude with every foot of development work. The presence of gold in such quantities in the lower workings of the property is a most encouraging sign and indicates that the richest portions of the mine have not yet been reached. Some shipments of ore from the new deposit are to be made at once. It is stated that the property never looked better in its history, and, with 112 men on the payroll, the output of ores is extremely heavy.

Camp Floyd District.

THE EAGLE COMPANY.—*Tribune:* The Eagle Gold Mining Company, with a capital stock of $150,000, and as many shares of a par value of $1 each, yesterday filed articles of incorporation, which recite that it is the intention of the incorporators to proceed at once with the exploration and development of a group of claims situated in Camp Floyd mining district, and consisting of the American Eagle, Bald Eagle, Eagle's Nest and Gray Eagle. The board of directors and officers consist of C. C. Goodwin, president; Edward E. Clark, vice-president; W. E. Huhhard, secretary and treasurer, and George L. Korner.

WASHINGTON.

OKANOGAN WILL MAKE THINGS HUM.—*Outlook:* Supt. Wheeler of the Bridgeport Mining and Milling Company, who went East last fall to raise money for mining purposes, has written back that he will return the 1st of April prepared to "make things hum" on Mineral Hill. This is good news, as the resumption of operations on the promising group of mines owned by that company will undoubtedly encourage other companies to move in the same direction.

WON FROM THE SAND.—Chelan *Leader:* Gold in paying quantities has been taken from the Columbia river sand on the Abercrombie bar above LaChapelle's by the use of the gold-saving machine invented by his brother, J. Porter Nicols, and we were shown the results of two cleanups, one of five hours, bringing $50, and the other of three hours, showing about $25.

WYOMING.

Laramie *Times:* There is considerable excitement at the Big Laramie, Wyoming, placer fields over a big strike that was made a few days ago. A prospect hole was sunk on one of the claims belonging to the Dodge City Placer Company to bedrock. They panned out from 75 cents to $1 per pan. The gold is different from any other that has been panned since the discovery in the camp, all of it being round or block pieces. In fact, it is the only place where bedrock has been struck, and it pans out beyond all expectations. If the weather continues to be pleasant, the Iron Mountain Company will send a gang of men there to work on its claims, preparatory to putting in a $30,000 plant.

Electrical Progress.

A Kansas City Electric Carriage.

A recent dispatch from Kausas City, Mo., said that a horseless carriage weut skimming along the smooth asphalt of Fonrteenth street in the vicinity of Cherry street, fulfilling Mother Shipton's prophecy that "Carriages without horses shall ruu," and terrifying two negroes, who saw sparks, and, apparently, sulphurous flames issuing from under it.

The vehicle was an electric carriage, of Kansas City invention and mauufactnre, and is the only one of its kind in the United States. There are several electrical carriages in New York city. The machine worked perfectly. A speed of eleven miles an hour was obtained.

The carriage is about the size of au ordinary vehicle. One seat faces the front and another one faces to the rear. A storage battery, composed of five series of five cells each, furnishes a current of sixty-seveu and one half ohms, and the cells are arranged in three tiers beneath the seats. The wheels are of wood, with India rubber cushious on the tires. The hind wheels, which are three feet two inches in diameter, have ou their inner sides a cast-iron flauge twenty-six inches in diameter and five inches wide. Power from the batteries is commuuicated to the flauge by a rawhide friction pulley, revolving from six hundred to one thousand times a miuute, and is capable of being elevated or depressed at will by the driver by means of divers, on which he places his feet. The steering is done by a tooth segment and attached to the axle of the fore wheels aud handled by a steering post, manipulated by the driver with his hands. The carriage can make quick, short turns. The storage batteries will run the machine about seven or eight hours. The carriage weighs about two thousand pounds, and is quicker and lighter thau the Europeau coaches.

A Tremendous Light.

The idea of an electric light which, fed by a current from a dynamo actuated by a forty-horse power engine, and giving 7000-candle power, can have its illuminating power intensified 35,000 times, is not easy to grasp. It means the production of a stream of light of about 250,000,000-candle power, and it is no wonder that the announcement that such a light is about to be used iu this country has been received with some incredulity in Europe. Yet, says the *Press*, this is the efficiency of the light which will be shortly erected at Fire Island for the illumination of the adjacent coast aud the protection of the fleet of ships eutering New York harbor. A remote suggestion of the power of this lamp may be arrived at by bearing in mind that an ordinary oil lamp is about 38 or 40-candle power, and then trying to imagine the combined beam of 3,000,000 lamps. The ordinary electric street light may be put down at 100-candle power, and 250,000 of these would about represent the strength of the Fire Island light.

The most powerful oil lamp yet made is supposed to shine out on a clear night for a distance of 35 or 40 miles, but the new light will flash its welcome rays to the iucoming European liners when they are 120 miles away. The light revolves rapidly and throws ont its beams with the intensity of speed of lightning. The motive power which actuates it is a simple clockwork arrangement contained iu a box two feet square, aud although the revolving portion of the light weighs fifteen tons, the mechanism controlling it is so delicate that the pressure of two fingers will turn it. The value of this marvelous lamp can ouly be determined by practical working, but it promises to represent an immense stride in the science of coast lighthouse illumination.

In his address at the recent convention of the Northwestern Electrical Association in Milwaukee, Mr. C. E. Gregory, of Chicago, said: "As the electrical business takes on age we find ourselves very near to the plane upon which we find the iron and woodworking industries. There was a time wheu we paid $100 for a series arc lamp, $800 a thousaud for carbons, and charged $1 per uight for commercial arc lights. We were then nursing the infant, but we have now on hand a giant who requires at least $600,000,000 per annum for supplies and expenses."

The Walker-Wilkins voltaic battery comprises a split cylinder of amalgamated zinc immersed in a solution of caustic potash contained iu a porous pot. This pot is placed iuside a cylindrical vessel having very numerous holes perforated through its wall. The iutervening space between the porous pot and the containiug vessel is packed with granulated carbon, that nearest the porous pot being powdered, and that nearest the perforated containing vessel in larger pieces. The current is collected by a perforated sheet nickel cylinder imbedded in the granular carbon. This cell has been tested by Professor Andrew Jamiesou, who reports that it is the best of its kind he has ever tested. A two-pint cell, weighing nineteen pounds and measuring 14x8¼ inches gave 1.457 volt on open circuit, 1.324 volt when .467 ampere was flowing, and 1.264 volt when 1.346 ampere was flowing. The output of a cell was kept at 1.1 ampere by varyiug the resistance, and the potential difference fell from 1.173 volt to 1.015 volt in 226.5 hours. The cell was then allowed to rest, and the electromotive force measured every twenty minntes to test its power of recuperation. At the eud of one hour it gave 1.260 volt; at the eud of two hours, 1.285 volt; at threc hours, 1.318 volt. The mean internal resistance of the cells varied from .112 to .161 ohm.

Russia's Metal Resources.

The Glasgow *Herald* says: "In the province of Daghestan, in the Russian Caucasus, rich deposits of quicksilver have recently been discovered, extending almost throughout the district of Kjnrinsk. The mercury is found imbedded in large sandstone blocks, and is of great purity. In different parts of the district other metals—such as lead, zinc, copper, sulphur and cobalt—have been met with, and the uatives have found at various placcs saud containiug a large perceutage of gold and a kind of yellow enamel color. Samples of these minerals have been sent to St. Petersburg for analysis. Russia also coutains about ten districts, mostly situate in the Ural mountains, where the gold-washers fiud diamouds every now aud then. The Ministry of Agriculture have sent to the Cape of Good Hope for the supply of thirty-nine crude diamonds in the matrix, it being assnmed that if the miners knew how the crude stones look diamond finds would be much more numerous."

The man who deliberately takes work below cost for the sake of handling money is dishouest, and he who does the same through ignorance may be forgiven for the first offense; but if he canuot help making such a mistake a second time he should get out of business. Dnring the dull times through which we have been passing I can quite understand how a man might be tempted to estimate low for the purpose of keeping things moving. The great trouble of this practice, however, is that customers will want these low prices contiuued wheu times get better and presses are needed for more profitable work. Cutting prices is easy, but restoring them is a harder matter, even if it can be accomplished at all.—American Bookmaker.

The most exteusive salt mincs in the world are located at Wieliczka, nine miles from Cracow, an Austrian city, in the crowu land of Galicia. These mines are worked on four different levels and have a total length of forty to fifty miles.

RUPTURE!

IT has beeu considered by the medical professlon that hernia—commonly called rupture—was iucurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But DR. J. C. ANTHONY, of 86 and 87 CHRONICLE BUILDING, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patieut no pain, and those living near enough do not lose auy time only while lu his office once or twice weekly. He guarantees every case he treats, and does not ask a man for a dollar unless he cures him, so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medical College, of New York City.

Where Cash is Scarce.

Scene. A village blacksmith shop in Bergen county, N. J., up near the New York State line.

The village blacksmith and his helper have just finished their day's work. The latter stops to lock the shop, while the former proceeds homeward. He has disappeared around the corner, when he suddenly reappears, on the dead run. "Hi, there," he shouts. "Don't lock up yet! Wait a minute!"

"Forgot something?" asks the helper.

"Yes."

"What?"

"The safe."

"Oh!"

The brawny blacksmith enters the shop and soon returns with a long board on his shoulder. It is covered with chalk marks.

"What is that for?" I ask.

"My safe."

"Your what?"

"My safe."

I know him well, and I accompany him towards his home. On the way he explains.

He has shod and "sharpened," he and his helper, thirty-eight horses during the day. Been on the jump from early dawn until nightfall. Had work enough to keep him in the shop all night, but he needs rest. Now is the busy season. Cold weather always brings a rush. Horses must be shod and old shoes sharpened to guard against the slipperiness of the roads.

"You should grow wealthy," I venture. "How much do you charge per horse?"

"From $2 to $2.50 for the four shoes."

"According to that you have made in the neighborhood of a hundred dollars to-day."

"Yes," says he, "and it's all on that board. I chalk it there to save time and then transcribe it into my books when I get home."

"Nobody pay you?"

He looked startled.

"One man wanted to pay me," he said, "but it's Friday, and I was afraid to take the money. I didn't dare to break in on the monotony of the day's proceedings."

"Will they ever pay you?" I ask.

"Oh, I suppose so. Some are good, some bad. We take their word for it. Everybody does hereabouts."

I ascertained these assertions to be true by interviewing the tradesmen. One merchant showed me his books, which proved that he had $10,000 outstanding.

"I get it in driblets," said he. "In some cases I let the people work it out. In others I take butter, eggs, milk, etc., in part payment of the debt.

"Some of our people never think of paying for anything they get. When one tradesman shuts down on them they go to another, and thus run through the whole gamut. When they have exhausted their credit in this town they go to the next town, and so on. By the time they have run through all the adjoining towns the local merchants have been compelled to sell out, and the 'free traders' strike the newcomers and begin it all over again.

"There is very little money in circulation in any of these country towns," continued the speaker. "Some time ago I marked a ten-dollar note and got it changed at the store of one of my neighbors. The butcher, the baker, the saloonkeeper, and so on, brought that bill to me at frequent intervals for me to change. It remained in town for several months, and then I finally banked it. Blamed if it didn't come back even then. A citizen here paid it to me. He had received it in change in a New York clothing store. I have framed it now."

Market for American Woods.

Eugene Germain, United States consul at Zurich, has been collecting a mass of information from Swiss manufacturers, builders and shipwrights as to the possibilities for American woods in Switzerland, and this he has embodied in a report to the State Department, giving in great detail the needs of each trade, prices current and other facts, all tending to establish his conclusion that there is an excellent opening in that country for American woods, provided they are of the first quality. The consul gives the names of Swiss importing houses that would be willing to undertake this business upon commission, and thus displace the woods now received from Hungary, Germany and England.

WITHOUT the power of attaching other men to his interests, a foreman cannot successfully regulate his workshop. In such cases he comes to be regarded as a mere taskmaker—an enemy to be beaten rather than a friend to be assisted, and the employer suffers from his moral defects. The possession of the attribute named, above and beyond the practical skill and scientific requirements previously referred to, will, in ninety-nine cases out of the hundred, gain the friendship of the employer as well as of the work-people, and thus the life of the foreman will be made not only endurable, but happy. No sadder picture can be imagined than that of an unprincipled man intrusted with absolute power.—Jos. Newton.

PATENT SOLICITORS.
ESTABLISHED 1863
Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S.F.

Market Reports.

The Markets.

SAN FRANCISCO, Feb. 21, 1895.

Silver again passed heyond the 60 cent limit during the week, a dullness in the foreign copper market interfering with sales. During last month copper was so much cheaper in London than in New York, that one French company bought 1200 tons in the latter city. Lead is unchanged.

At last a premium is announced on gold—three-eighths of one per cent. This was on Monday, and was occasioned by the scarcity caused by the demand for the new U. S. bonds. The premium is not likely to be permanent.

New York Metal Market.

NEW YORK, Feb. 21.—PIG IRON—Scotch, 19@20c; American, 9.50@12.50c.
COPPER—Brokers', 9¾c; exchange, 9.90c.
LEAD—Brokers', $3.02½; exchange, $3.10.
TIN—Straits, 13¾c; plates, ——c.
SPELTER—Domestic, $3.20.

Mining Share Market.

SAN FRANCISCO, Feh. 21, 1895.

The stocks were stronger during the early part of the week, the demand exceeding the supply. On Wednesday prices fell off again, the shorts making the usual effort, despising not the day of small things.

For the first time since June, '89, the Eureka Con. levies an assessment. It used to he a good dividend producer, having paid ten dollars in dividends to one dollar it has ever assessed.

The remote prohahility of the Hale & Norcross mine getting some money from a judgment in one of the Fox suits gave the stock a lift early in the week. Work in the mine has been resumed.

At the annual meeting of the Standard Consolidated Mining Company of Bodie, last Monday, 76,641 shares of the capital stock were represented.

The following directors were elected: Thomas H. Leggett, William Borrowe, P. M. Lilienthal, A. P. Brayton and J. W. Pew of San Francisco, and W. H. Oscanyon and C. H. Badeau of New York.

During the past year the receipts of the Standard Consolidated, including balances carried over, aggregated $259,790.53; disbursements, $206,605.44, four quarterly dividends of ten cents each, amounting to $37,805.60 included; halance on hand, $53,185.09. Another quarterly dividend of ten cents per share was declared, payahle March 20th.

C. H. Fish, president Con. California & Virginia, is visiting the Comstock. It is expected when the new survey of the late workings is finished that an increase in the force in the mine will he made and active prospecting carried on.

D. C. Bates has been elected director of the Con. New York Mining Company, vice C. C. Harvey, deceased.

Superintendent Boyle of the Alta announces the shipment of hullion valued at $10,500, heing the cleanup of the recent run of the mill.

The directors of the National Lead Company declared a quarterly dividend of 1¾ per cent on the preferred stock, payahle March 15th.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitore for Pacific Coast.

FOR WEEK ENDING FEBRUARY 12, 1895.

534,196.—AMALGAMATOR—A. & J. W. Carlson, Lagrande, Ogn.

533,870.—PIPE FASTENER—H. N. Davies, Rockford, Wash.

533,886.—STRAW BURNER—F. Girtanner, Los Angeles, Cal.

533,891.—SASH FASTENER—J. E. Hartmann, Tacoma, Wash.

533,901.—PLANT SUPPORT—J. E. Hutchinson, S. F.

534,119.—LATHE—Matthew & Collier, Tacoma, Wash.

534,226.—BILL FILE, ETC.—T. F. McGarry, Pasadena, Cal.

534,002.—BOILER—D. J. Perkins, Truckee, Cal.

534,014.—ANIMAL TRAP—J. Sherrett, Norfolk, Ogn.

24,041.—DESIGN—HAME HOOK—N. S. Wilson, Meridian, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. In the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the ehortest possible time.

Justinian Caire.

Tbe above is a name familiar to many miners on this coast who for years have had him provide them with mining and milling supplies for placer, quartz or drift mining operations, years of successful experience enabling him to supply everything in that line of a guaranteed quality and at a low rate. One of his specialties is the silver plated amalgamating plate, which is in such high favor among mill men. Each plate is made of the best soft Lake Superior copper, guaranteed to have full weight of silver, and made throughout in the best manner.

In assayers' and chemists' supplies his stock is complete. Among other things he furnishes a $90 outfit for prospectors, comprising all requisite chemical apparatus for ordinary requirements. Besides being agent of the San Francisco Novelty and Plating Works, he also has on hand a large stock of the latest improved drawing instruments, carries a full supply of brass, steel and iron wire screens, optical instruments, chemicals, reagents, hone ash, commercial acids, copperas, bluestone, litharge, etc., and makes a specialty of cyanide of potassium. Furnaces, cupels, English, French and German glass and porcelain ware, crucibles, assay weights and balances, retorts, etc., are kept in full stock. The latest and most reliable text books on chemical and metallurgical subjects are kept in stock. His place of business, 521 and 523 Market street, San Francisco, is headquarters for the trade, and the purchasing public get the benefit of the closest quotations on all articles kept in stock.

Assessment Notices.

FAIRFAX VILLA COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Fairfax, Marin county, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 19th day of February, 1895, an assessment, No. 2, of one hundred dollars ($100) per share was levied upon the Capital Stock of the Corporation, payable immediately in United States Gold Coin to the Secretary, at the office of the Company, Room 56, No. 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 26th day of March, 1895, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the 9th day of April, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

J. STADTFELD, JR., Secretary.

Office—Room No. 56, No 309 Montgomery street, San Francisco, California.

CHALLENGE CONSOLIDATED MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Gold Hill, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the nineteenth (19th) day of February, 1895, an assessment (No. 18) of Five Cents (5c) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the company, Room 35, third floor, Mills Building, corner Bush and Montgomery streets, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the twenty-sixth (26th) day of March, 1895, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on TUESDAY, the sixteenth (16th) day of April, 1895, to pay the delinquent assessment, together with cost of advertising and expenses of sale.

By order of the Board of Directors.

C. McCOY, Secretary.

Office—Room 35, third floor, Mills Building, corner Bush and Montgomery streets, San Francisco, California.

BOOTH GOLD MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Auburn, Placer county, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the eighteenth day of February, 1895, an assessment (No. 5) of Two (2c) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, No. 310 Pine street, Room No. 28, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the twenty-fifth day of March, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on WEDNESDAY, the seventeenth day of April, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

GEO. R. SPINNEY, Secretary.

Office—No. 310 Pine street, Room No. 28, San Francisco, California.

BULLION MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Virginia district, Storey county, Nevada.

Notice is hereby given that at a meetiug of the Board of Directors, held on the 21st day of January, 1895, an assessment, (No. 44) of 10 cents per share was sold on THURSDAY, the 21st day of March, 1895, levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the company, Room 21, No. 331 Pine Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 26th day of February, 1895, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

R. R. GRAYSON, Secretary.

Office, Room 21, No. 331 Pine street, San Francisco, California.

INYO MARBLE COMPANY OF CALIFORNIA.—Location of principal place of business, San Francisco, California; location of works, Inyo, Inyo County, California.

Notice is hereby given, that at a meeting of the Board of Directors held on the 21st day of January, 1895, an assessment (No. 26) of ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, Room No. 13, third floor, Mills Building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 6th day of March, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on FRIDAY, the 5th day of April, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

W. W. SARGEANT, Secretary.

Office—Room 13, third floor, Mills Building, San Francisco, California.

DUMBARTON LAND AND IMPROVEMENT COMPANY.—Location of principal place of business, San Francisco, California. Location of works, in the counties of Alameda and Santa Clara, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 22d day of January, 1895, an assessment (No. 7) of 12½ cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, No. 214 Pine street, room 55, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 28th day of February, 1895, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on THURSDAY, the 21st day of March, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

JABEZ HOWES, Secretary.

Office, Room 55, 214 Pine Street, San Francisco, California.

THE CALIFORNIA DEBRIS COMMISSION, having received applications to mine by the hydraulic process from W. Thomas et al., in the Central Hill Mine, Douglas Flat, Calaveras Co., Cal., to impound tailings behind stone dams in ravines; from Giovanni Rossi, in the Kate Gray Mine, near Volcano, Amador Co., Cal., to impound tailings behind log and brush dams below mine; from J. E. Newsom, in the Shealor Mine, near Volcano, Amador Co., Cal., to impound tailings benind log, rock and brush dam in Sutter Creek; from Giani Demartini et al., in the Rail Road Hill Gravel Mine, near Fourth Crossing, Calaveras Co., Cal., to impound tailings behind a dam on flat ground; and from James Slater, in his mine near Brownsville, Yuba Co., Cal., to impound tailings behind York Mining Co.'s dam, gives notice that a meeting will be held at Room No. 92, Flood Building, San Francisco, Cal., on Feb. 25th, 1895, at 1:30 P. M.

WANTED FOR CASH,

Second-Hand 3½-Foot

HUNTINGTON MILL

IN GOOD CONDITION.

C., Box A, Mining and Scientific Press.

The Explorers' and Assayers' Companion.

A Third Edition of Selected Portions of the "Explorers', Miners' and Metallurgists' Companion."

By J. S. PHILLIPS, M. E.

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying and Metallurgy.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay has been kept as free from formulæ as possible. The work is written for practical men, and all the explanations and discriptions are clear and to the point. It is so prepared that it is useful to uneducated men ae well as scientists.

Price $6.00 postpaid. Sold by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco,

Coast Industrial Notes.

—The city savings banks hold deposits aggregating $100,000,000.

A carload of salmon is being daily sent East from Gray's Harbor, Wash.

Watsonville, Santa Cruz Co., has shipped two carloads of apples to England.

The Western Iron and Steel Co. is about starting up its Lake View, Wash., rolling mill with 125 men at work.

A second shipment of a cargo of 600,000 feet of lumber to Hawaii has been made from Port Angeles for the Honolulu Railroad.

—Up to last Tuesday 14,447 names were on the registered list of the unemployed at the Bureau, 60 Eighth street, this city.

—Columbia river fishermen will hereafter have to pay an annual license of from $2.50 to $200, according to the manner of catching fish.

An electric line between Tacoma and Seattle is projected. Between the railroad and Sound steamers the new line will hardly prove remunerative.

Senator White last Monday presented a memorial from 20,000 citizens of southern California requesting the early construction of a breakwater at San Pedro.

It is reported in Victoria that $2,000,000 have been subscribed in Montreal towards building a smelter at Naksup, and that the scheme is backed by the C. P. R.

The Canadian Pacific earnings for the week ending February 7th, were $331,000 against $384,000 for the corresponding period last year, being a decrease of $53,000.

A company has been organized in this city, with $1,000,000 capital stock, with a view to full representation of California manufactures at the coming exposition in the City of Mexico.

"The lumber market is booming. Sugar pine is now worth about $80 a thousand and is still on the rise. Other classes of lumber have gone up, too," says the Dunsmuir *News*.

W. L. Keene & Co., of Vancouver, have arranged for a line of sailing vessels to leave San Francisco every fortnight, carrying nonperishable goods to Vancouver and B. C. points.

—The Southern California Railway Co., which some years ago changed from wood to coal, has about completed arrangements for locomotive steam making by burning crude petroleum.

—It is estimated by hotel and railroad men that there are 20,000 visitors already in southern California, and that the present severity of Eastern weather will nearly if not quite double that number.

One hundred thousand negroes will leave Alabama, Georgia and Louisiana for northern Mexico in the next few months. A colony has been founded under the auspices of the Mexican Government.

—The annual Fiesta or Carnival at Los Angeles, Cal., will take place this year from the 15th to the 20th of April, comparing in splendor and interest with the Carnival of Rome or the New Orleans Mardi Gras.

—The Seattle & Lake Washington Waterway Company will mass its excavating plant. The dredger now in use at Olympia and the one at Portland will be brought into requisition. The latter machine was built at a cost of $124,000.

The San Francisco owners of the big Port Discovery, Wash., mill, whose machinery has been idle for several years, have arranged for the outlay of $100,000 in improvements and working capital, and the mill will soon be operated at its full capacity of 300,000 feet daily.

—Surveyor-General W. S. Green calls for bids for the resurvey of three southern California forest reserves—173 miles to establish the lines of the San Bernardino forest reserve, 154 miles for the San Gabriel and forty miles for the Trabuco Canyon reserve—according to executive proclamation.

—San Francisco is soon to inaugurate an industry that has hitherto been confined in this country to New York City—that of whalebone cutting. While much of the world's supply of whalebone is landed here from the whaling ships, it has hitherto all been sent to New York and London to be cut for use.

—The White River Water Power Co. has been incorporated in New Jersey, with a $2,000,000 capital stock, to build an immense electric power plant in northwestern Washington. It is intended to tap the White river near Buckley, and carry the water in an open ditch to Lake Tapps, near Sumner, where a storage reservoir will be built. From there the water will have a 450-foot fall to the power house, where it is intended to have a generator capable of developing 25,000-horse power.

The Treasury Department decides that on the exportation of steel rails measuring twenty feet in length and weighing twelve pounds to the running yard, manufactured by the Pacific Rolling Mills wholly from imported steel blooms, a drawback will be allowed equal in amount to the duty paid on the imported material used in the manufacture, less the legal deduction of one per cent. The quantity of the material so used may be determined by adding to the net weight of the exported rails ten per cent of such weight.

—Last Tuesday the California Wine Makers' Corporation sold to the California Wine Association 18,000,000 gallons of wine at twelve and one-half cents per gallon—the largest transaction of the kind in the history of the country. The wine dealers also bought six large wineries, situated at St. Helena, Napa, Livermore, San Jose, Glen Ellen and Esparto. By the terms of the contract 4,000,000 gallons are to be delivered and paid for this year, at the price named, and 5,000,000 gallons in each of the succeeding three years, at the then ruling rate.

—Evidence of the extent to which our wheat trade with Germany has suffered by the competition of the Argentine Republic is contained in a report to the State Department by Frank H. Mason, United States consul-general at Frankfort, upon the German wheat imports for the past three years. In 1892 the United States shipped to Germany 6,302,130 tons of wheat. The next year this dropped to 3,149,282 tons, and in 1894 the imports were but 3,054,669 tons. Meanwhile Argentine seemed to have gained about what we lost of the trade, for the imports of wheat from that country into Germany, amounting in 1892 to but 661,697 tons, had swelled in 1893 to 1,513,961 tons and in 1894 to 3,196,190 tons.

—W. F. de Land, who is connected with the Lower California Pearl Fishing Company, reports that the past season has been quite successful. The company has a number of schooners and forty launches, each of the latter being equipped with machinery and diving apparatus. About 600 men are employed by the company, and they fish for 1000 miles along the border line of Guatemala, around the coast of Oaxaca and Guerrero, and up to the mouth of the Colorado river in the Gulf of California. Quite a number of pearls were found this year, some of them being very large. One weighed 17 carats, another 15, another 12 and still another 10. The pearls are white, black, and different shades of green and blue—the green and blue pearls being found in no other fisheries in the world, and they are very valuable.

—John S. Morgan of Selby, gave an exhibition on the bay this week, of his new device of driving a vessel over the surface of the water without paddles, sails, wheels or propeller. His launch, the Eleanor, has a gasoline 6 H. P. engine, and steams seven knots an hour. Water is injected through valves in the bottom of the boat amidships, and forced out through an inch and a quarter pipe in the stern. The delivery tube is below the surface, and the resistance which the rejected stream meets when it encounters the dead water outside pushes the boat ahead. Mr. Morgan claims that his method of ejecting the water by a single-action pump, in a succession of separate strokes, is an improvement over the continuous stream experimented upon by the marine engineers who have been attempting this new means of propulsion. The boat can be stopped or backed by reversing the current passing through the hull and driving it out through the bottom valves, the direction of their insertion being such that the ejected water is driven toward the boat's head.

FOR SALE.

1 Latest Improved Bruckner Furnace.
2 Chlorinating Cylinders of cast iron, lead lined.
1 set Krom Rolls.

The above in use but a short time. For sale cheap. Address **L. C. S., Box A., Mining and Scientific Press Office, S. F.**

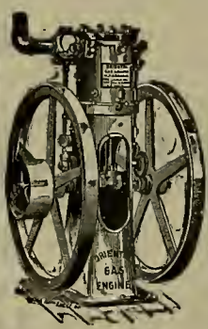
The Oriental Gas Engine



IS THE BEST because it combines simplicity of construction with power and economy of space. It can be run with natural or manufactured gas or gasoline at a cost of 20 to 25 cents per horse power per day.

It can be used for pumping purposes, as well as for all purposes where a perfect engine is required, with the advantage of lessening the risk of explosions. No licensed engineer at a high salary needed to operate it.

Send for circulars and prices if a good safe engine is what you need.

The Oriental Launch is Perfection.

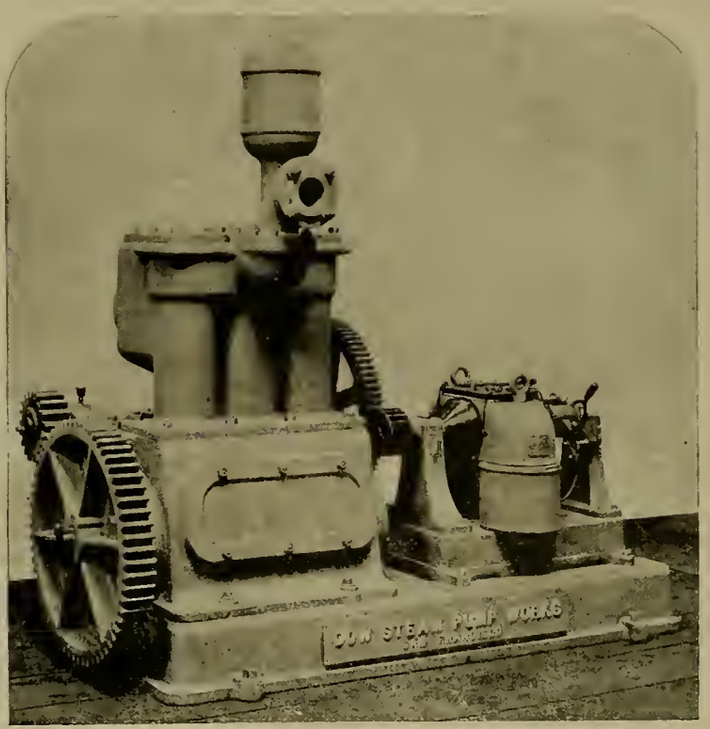
Largest Freight Wagons in the World.

The wagon shown herewith was designed and made by the Best Manufacturing Company, San Leandro, Cal., and was built especially for steam freighting in connection with the company's traction engine. The capacity of these wagons is sixteen tons each, and they have sufficient wheel surface to sustain that amount without injury to the roads—in fact, they pack the road. The dimensions and description in detail are as follows: Size of axles, four inches in diameter; front wheels, four feet ten inches high—tire, sixteen inches in width; rear wheels, six feet high—width of tire the same as front wheels; length of bed, nineteen feet six inches; width of bed, four feet six inches; height of bed, six feet. They are made wholly of iron and steel, except the bed which is of wood. The front wheels track somewhat wider than the rear ones, for this reason: The continual hauling over the road and the wagons always running in the same tracks naturally cuts down the road into ruts to a certain extent and makes it uneven. This the makers wished to overcome, and as the engine wheels are twenty-six inches wide they designed the front wheels of the wagons so that the tire tracks would lop one-half the width of the engine wheels on the inside. The rear wheels of the wagons travel so as to lop one-half the width of the inside of the track of the front wheels, thus packing the road smooth and firm and always clear of ruts where the wheels travel.



DOW'S IMPROVED TRIPLEX POWER PUMP.

Triplex Power Pump.

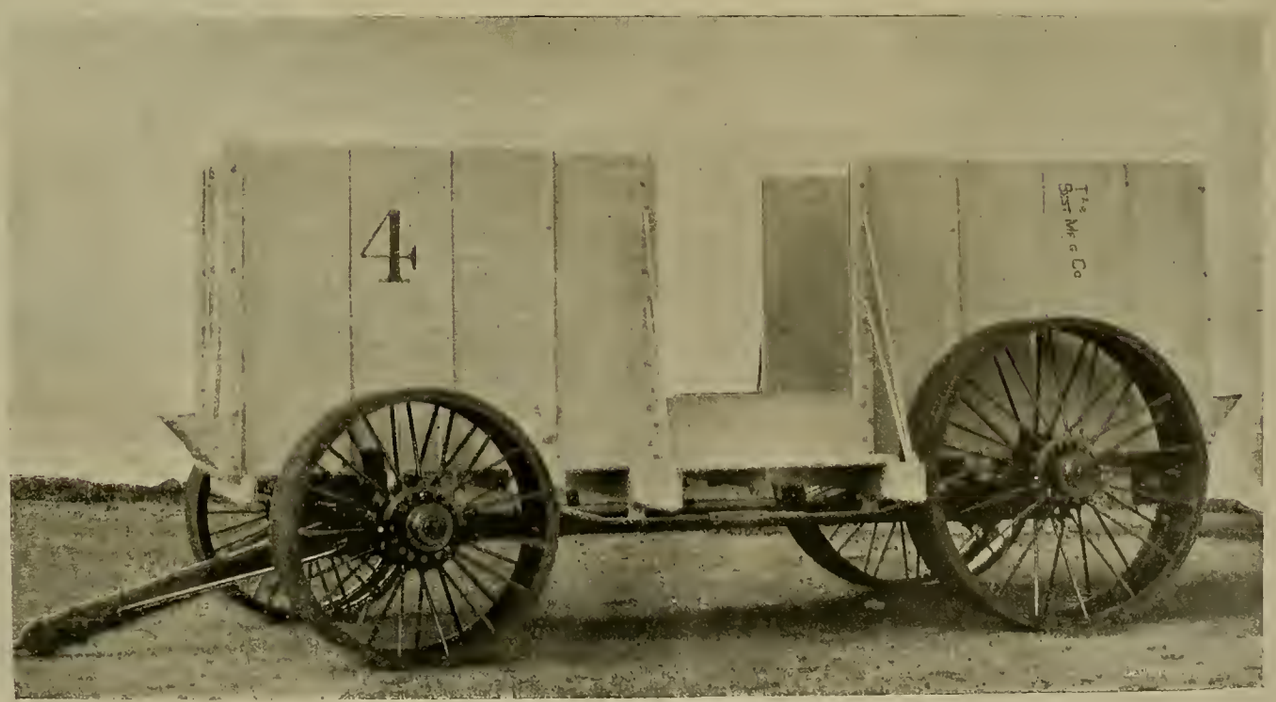
The Dow Steam Pump Works, 114 116 Beale St., have issued a handsome catalogue of their improved power pumping and hydraulic machinery which present data of value to those interested in steam and hydraulic engineering. Herewith is illustrated one of their improved triplex power pumps of vertical mining pattern, for mine station pumping with electric motor, as successfully applied to mine station pumping, and for situations where water power is available for generating electricity.

The crank shaft and connecting rods are operated in a closed chamber in which oil is retained and the connections made self-lubricating. A high rate of speed can be obtained without pounding or detrimental wear, thus obviating constant and careful adjustment.

They have patterns for this class of pump up to a capacity of 300 gallons per minute, and height of 300 feet.

They can furnish pumps with or without electric motors.

The Dow pumps have been endorsed by the United States Government by ordering them in the construction of battleships and cruisers, and are of acknowledged value.



FREIGHT WAGON BUILT BY THE BEST MANUFACTURING COMPANY.

It is almost a forgotten fact that from 1793 to 1873 American silver dollars were at a three per cent premium in Europe, and went eastward almost as soon as coined. Times change.

Nearly eight per cent of the union workmen in Glasgow, and eighteen per cent of the union shipbuilders there, are out of employment, owing to dull times.

THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 142.
MISCELLANEOUS.—Concentrates, 130. Telephones in Mining; Prospecting Enterprises in Nevada, 132. An Old-Time Mine Hoisting Apparatus, 133. Men Whose Labor is Slowly Fatal; About Gold Mining; Personal; Obituary; Protecting Mineral Lands; Book Review, 134. The Mineral Hydrocarbons, 136. Tremendous Power; Hot Salt Solution for Relief of Short Hemorrhage, 141. Recent Patents, 142. Coast Industrial Notes, 143.

WITH the advent of the new railroad comes promise of increased business for the wood-workers and iron-workers of the State. It goes without saying that everything in iron or steel from a spike to a locomotive can be made and should be furnished here.

THE coming Mexican International Exposition affords opportunity to San Francisco manufacturers of mining machinery to enlarge their market. There is a splendid field in Mexico for mining machinery of approved make, a fact which our local manufacturers should not be backward in realizing.

THE State Manufacturers' Convention, on the 19th inst., at the Chamber of Commerce in this city, is an important and necessary move. The main proposition is union and organization, the fostering of new industries, and, in general, the industrial emancipation of the State. Under rightly related conditions there is no valid reason against such consummation, which must manifestly result in mutual prosperity.

UNDER "the Timber Land act," any one may take up 160 acres government land, valuable chiefly for stone, complying with all provisions just as in the taking up of land for the timber on it—the payment of $2.50 per acre, publication of the required notice, filing of the affidavit of publication, appearance with two disinterested witnesses before the local land office register, etc. In such cases the non-mineral character of the land must be sworn to.

THAT gigantic gold mine referred to in these columns some time ago, enabled its directors and stockholders to declare a $7,000,000 dividend last month. It is too good a thing to let get this far west, the opportunity to invest being limited by Messrs. Cleveland and Carlisle solely to Wall Street and English buyers. The whole business discredits the nation, but that is of minor importance. California stock deals sound slim and meager alongside such transactions, whereby a profit of seven millions is made certain in a gold mine without even one assessment.

A LOS ANGELES SUBSCRIBER questions the statement last week in "Concentrates" that gold during the week had commanded a premium of ⅜ of 1%. Here are the facts in detail: On Friday, in New York City, there was a draft on the depleted gold reserve of $665,000. Of that sum Russell Sage withdrew $550,000. He had no use for it for export purchases, but put it in a storage vault. He had gold bullion additional amounting to $450,000. A subscriber to the bond syndicate wanted the gold, and, seeing a good profit, paid ⅜ of 1%, or $3750 premium to Sage for the million to buy bonds with. The fact is of common report in the New York papers. The PRESS draws no political, that is partisan, conclusion. The matter was boiled down to a one-line statement, but was and is actually true.

New Gold Processes.

Nearly ninety years ago it was observed that gold was soluble in cyanide of potassium, but for more than half a century the fact was a chemical curiosity, a laboratory demonstration, with no practical application. In later years the matter has received world-wide attention among metallurgists, and for the last five years "the cyanide process" has in some instances revolutionized gold-saving methods.

In the last few weeks from London and Arizona come accounts of gold extraction processes based on the cyanide system, with, it is claimed, such improvements as will result in its more extended efficiency. The importance of the interests involved and the widespread interest in the subject justify notice.

Assuming that our readers are in general conversant with the principles of the MacArthur-Forrest system, which may be considered the standard, it may be said of the process now being tested in two Arizona mines that it is an elaboration of that treatment. There the ore is crushed to a certain fineness, depending on the character of the gangue, then placed in leaching vats, having the usual false bottoms for filtration, and a solution of cyanide of potassium and other chemicals of determined solution is run over the pulp and is left to stand for some hours. It is then drained off, and another charge is used of less strength, which is in turn also drained off. The pulp is then washed with clean water, which leaches all the gold and silver, and leaves the tailings ready for discharge either in cars or to be sluiced away. The filtered solutions and washings from the leaching vats are passed through a precipitating box, which is practically an electric cell, the positive plate of lead and the cathode or negative pole being mercury. A dynamo supplies the current, which is of sufficient pressure to decompose electrolytic liquid, a circulation being thus kept up. The solution formed of the double cyanide of gold and silver, as it goes along yields up these metals under the action of the current, and is gathered on strips of copper connected with the mercury. The solution can be used over and over again by re-enforcing it to the desired percentage, and it is asserted by the experimenters that by this electro-chemical cyanide process a capacity for handling 10,000 tons of pulp per month will run at a cost of about $2 per ton. Bullion recovered by this method is claimed to be in fineness in excess of that which is zinc precipitated.

The London process is being praised at unusual length in sundry London journals. The originator of this latest announcement in the gold-mining world is H. Livingstone Sulman, an analytical chemist, who, though he never saw a gold mine, is confident he has a discovery that is of the greatest practical merit. This confidence seems largely shared by his confreres.

He denies the necessity of oxygenation, hitherto considered so essential a part of the cyanide system. He asserts that he can dispense with oxygen altogether, and make the cyanogen all potential. Discarding that factor in the MacArthur-Forrest equation he uses a haloid salt, a bromide of cyanogen, and adding a small quantity of this to the ordinary cyanide solution, claims to thus secure unprecedented rapidity in the desired result. Concentrates ordinarily requiring two weeks can, it is asserted, be successfully treated by the Sulman process in less than forty-eight hours, no matter what the quality of the ore, and the slimes, hitherto found so recalcitrant, can, he asserts, be leached with success. His process for slimes is to add a soap solution, stir vigorously and clot with lime, thus making the mud granular and susceptible of leaching. When it is borne in mind that while 600,000 ounces of gold were produced from battery tailings in the Witwatersrand district, South Africa, in '94, an estimated value of $1,500,000 was lost in the slimes during the same time by inability to treat them, it will be seen what success in that direction means. Mr. Vautin, a colleague of Sulman's, asserts that the extraction of gold from slimes in this manner is successfully demonstrated. This matter of securing the gold from slimes has been given practical attention at the mines. Attempts have been made to prevent or obviate their formation; or by substitution of air for water at the stamps. It has been tried to work slimes holding over one-half an ounce to the ton, and persistent disintegration has with such rich slimes extracted the gold at a cost about equaling in value the output, being poor inducement for experiment with slimes carrying but one-half or one-third such quantity of gold. The Sulman-Vautin process would with slimes alone, if successful, make every such mine worth far more than at present.

Beside discarding the oxygen of the present process, the London chemists claim to have also done away with the necessity of the zinc shavings, substituting an emulsion of zinc fumes, saving, according to their view, the expense of smelting.

A minor point, not wholly devoid of interest, is the assertion of Mr. Sulman that the reason that "float gold" floats on water is the "surface tension". Were this "surface tension" counteracted or neutralized, he claims that annoying feature would disappear. This also he claims to be able to overcome. He says "a morsel of common soap" will destroy this surface tension.

The greatest interest is manifested in British mining circles over this new announcement. One company has already bought patent rights for South Africa; another for Australia, and a third corporation has secured similar rights in Mexico. If the discoverers and the believers in them be not egregiously deceived, the problem of cheap extraction of gold in the class of ores most susceptible of treatment by that general process is nearer solution than ever before.

The idea is not wholly original. Less than six months ago an assayer in northeastern Washington wrote to the MINING AND SCIENTIFIC PRESS that he had discovered that bromine could be substituted in the cyanide process, with a request that nothing be said about it till he had practically demonstrated and secured his claim. In other quarters the same chemical possibility has also been noted. Englehardt has a bromine process claimed to be successful. Nor is bromine the only substitute for oxygen in this oxidizing process. Sodium peroxide has given similar satisfactory result in laboratory experiments. But it were invidious to withhold a single laurel from the wreath that will crown the successful discoverer in practical fields of science, whoever or wherever he may be. The London announcement, briefly synopsized above, is making tremendous stir, and upon the proven results of rigid tests and practical experience will depend its outcome.

HOW THE THREATENED legislative attack on the California State Mining Bureau is viewed elsewhere is well exemplified by the following, which is but one of such letters recently received:

—OFFICE OF—
THE MIXSELL MILL.
PHILIP MIXSELL, MGR.

One of the Most Complete Concentrating and Stamp Mills in the State. — *Also Manager of Several Producing Mines.*

IDAHO SPRINGS, COLO., Feb. 23, 1895.

Mr. J. F. Halloran:—Enclosed find $3.00 for another year of your most excellent journal. If your State Legislature repeals the State Mining Bureau bill it will be taking a step backwards. The reports from that Bureau are of the utmost value, and I know it has been through those reports that California has secured so many Colorado mining men of means. Yours very truly, PHILIP MIXSELL.

THE articles in the PRESS last July on the mines and mineral possibilities of Mariposa, are bearing abundant fruit in the renewed attention given that mining region. No part of California promises more immediate activity than the Coulterville district, and the preparations are on a scale commensurate with the interests involved. A 300 stamp mill, a railway from it to the different mines owned by the new company, electrical generators, etc., evince the change from the sleepy old inertness to the new era when from 600 to 800 men will be busy adding millions from Mariposa to the world's golden wealth.

SEVERAL inquiries have recently been received as to whether gypsum is or is not considered a mineral under the mining law. In answer it may be said that gypsum can be located in the same general manner as a placer claim—twenty acres—the Commissioner of the General Land Office so interpreting the matter. The most recent location of a gypsum claim that has came under our observation is that of Chas. King, of San Benito.

Concentrates.

THE Keystone mill, at Amador City, is again in operation.

THE Standard Con. Mining Co. pays a 10-cent dividend on the 20th inst.

A NEW STAMP MILL is about completed on the Oro Fino (Montana) gold mine.

ANOTHER effort is making to develop the Eutopia, Lake Co., quicksilver mine.

THE new forty-stamp mill at the New London, Plymouth, Amador Co., is about finished.

THE Hayden Hill Mining Co., Hayden Hill, Lassen Co., are about to put in a ten-stamp mill.

LABOR TROUBLES have closed up the Morning Glory mine and mill on Turkey Creek, Arizona.

THE Alaska-Mexican Gold Mining Company will shortly add sixty stamps to its mill on Douglas Island.

IT is reported in Prescott that G. W. Hull, of Cerome, has bonded his mining properties in that camp for $160,000.

DR. SCHLOESSER, of Chicago, has bought a controlling interest in the Evening Star mill and mine near Susanville.

BETWEEN $3000 and $4000 in gold has been taken by sluicing from Gold and Demon creeks, Alaska, since December 1st.

J. A. MAXFIELD, a well-known Comstock miner, was recently killed by an exploding blast in a mine at San Miguel, Mexico.

THE Delano Mining and Milling Company has filed articles of incorporation; capital stock, $500,000; principal office, Boulder, Col.

THE January output of the Butte & Boston (Montana) mine was 1,456,800 pounds of copper, 103,400 ounces of silver and 205 ounces of gold.

A SALT LAKE company is getting ready to work the tailings at the Voorhei's & Barney sulphuret works, in Drytown, by cyanide process.

THE Arizona Copper Company has been incorporated in Philadelphia; capital, $50,000; to operate in Boulder county, Col., and Arizona.

IN the Alaska mine, at Pike City, Sierra Co., last week, a large ledge of fine ore was uncovered. The quartz shows plenty of free gold.

THE *New Era* reports that a San Francisco mining expert has leased the Jenkins mill at Kennedy, Nev., and intends to put it in operation.

THE new owners of the Silver Bow Basin mines, Alaska, have decided on the building of a mining plant to rival the Treadwell in size.

IT is again asserted that the Mammoth and Collins mines, Arizona, are to be sold to an English company who will operate them on a big scale.

B. MCCORMICK, employed at the Providence mine, Nevada City, was killed last Sunday by being caught in the spur wheel of the hoisting rig.

THE Octopus Gold Mining and Milling Co. has finished a twenty-stamp mill in Bruno district, Elko Co., Nevada. It will be run by water power.

MESSRS. GREEN & RYAN, Saginaw, Mich., lumbermen, have bought three claims, the Eureka group, in the Slocan district, for the reported price of $50,000.

THE coal output in the different mines of Wyoming for the past year was 2,202,000 tons. The number of fatal accidents was thirteen, out of 3453 men employed.

"IN general," says the Denver *Mining Industry*, "it may be presumed that no part of the United States has better facilities for cheap mining than California."

TO DATE the Hope mine of Montana has paid $593,250 in dividends. The latest was a $10,000 dividend January 23d. Nearly 100 men are now employed in the mine.

THE Home mine on Deer creek, Nevada county, which lay idle for nearly fifteen years, is now being worked with very flattering prospect for a resumption of dividends.

THE De Lamar Mining Company of Idaho is now putting in a complete arc light plant in addition to the incandescent plant, to light their mills and the streets of the city.

THE War Eagle, Trail creek, B. C., was jumped last week because the foreign company, now the owners, had not registered in British Columbia. Costly litigation may follow.

AT Slate creek, Wash., the Excelsior group, owned by Carish, Temply and Beuson, of Anacortes, have been bonded to a New York syndicate for $40,000 and cash payment of $2500.

THERE is a bill before the Nevada Legislature which provides for the removal of the State capital to any city or town in the State which will contribute $100,000 into the State treasury.

THE Excelsior Company have suspended hydraulic operations at Smartsville. They will probably dig a considerable piece of ditch, and move several hundred feet of water pipe before resuming.

THE cyanide tanks at Wickenburg, Arizona, are reducing Vulture tailings, two bars of gold of the value of 65 and 72 ounces each being recently received in Prescott. The tailings average $5 per ton.

AT Juneau, Alaska, N. H. Gaddis has been acquitted of stealing $1000 worth of amalgam from Thorp & Bounifield's mill last August, and $3500 from the Ebner mill in October and November last.

THE Gem (Idaho) mine laid off about forty-five men recently. But little more work than sinking the shaft and other development work below the tunnel level will be prosecuted for the next four months.

A STRIKE is reported in the O. & C. mine, at Henley, Siskiyou Co. Twenty-seven tons of ore are being treated at the Selby Works. Some of the ore runs $300 to the ton. A five-stamp mill is being built.

THE Kootenay Water Supply Company are putting in a dam at Waneta to supply water power to pump a thousand inches into the main ditch of the Kootenay Hydraulic Company for use in washing their gravel banks.

THE Mountain View Mining Co., which recently bought the Star and Roebuck mines, near Fine Gold, Madera, propose employing about fifty men when their new twenty-stamp mill, now being contracted for, is in operation.

THE passage of the bill for establishing a coinage mint in Denver, to take the place of its present purchasing mint, and coin the gold where it is produced, recognizes Colorado's importance as a producer of the monetary metals.

J. H. NEFF, of Placer Co., learning that the funds of the Miners' Association would not warrant the publication of the proceedings of the last convention, became personally responsible for the payment of the bill, and the work is going on.

THE following are recent incorporations: The Pinon Mining and Milling Co., San Francisco, capital stock, $20,000,000; the Jones Creek Mill and Mining Co., Crescent City, $80,000; Northwestern Mining Bureau, Seattle, $50,000.

THE Morning Star Company, Iowa Hill, has declared another dividend of $3 per share on the capital stock. This makes the second dividend in a month by that mining company, the first one being $4 per share. Most of the stock is owned in Grass Valley.

LAST Tuesday Senator Perkins presented in the U. S. Senate the joint resolution of the Legislature of California for free coinage of silver; also the resolution urging the immediate appropriation of $20,000 for the support of the California Debris Commission.

THE Alaska-Treadwell Company makes the following report for the month of December, 1894: Ore milled, 19,807 tons; sulphurets treated, 345 tons; bullion from sulphurets, $14,625; bullion shipped, $44,347; bullion yield per ton of ore crushed, $2.24.

THE Denver smelters and large producers of gold have been sending their gold East in bars the past month on account of receiving one-half per cent higher price than the Government pays for coinage purposes there and at Philadelphia, making gold a commercial commodity.

GOVERNOR BUDD has transmitted to the California Senators and Representatives in Congress, in accordance with the request of the Legislature, Assembly Joint Resolution No. 20, relative to securing immediate attention from Congress to the United States Debris Commission.

THE proprietor of the Golden Shaft mine, at Dutch Flat, has been notified by the California Debris Commission to cease hydraulic mining. In answer it is asserted that the Golden Shaft is a drift mine pure and simple, the gravel being taken out of a ninety-foot shaft.

AT a meeting of the officers of the County Miners' Association in Auburn last Saturday, it was decided to take such steps as would be necessary to obtain funds for the support of the State Association. Two hundred dollars was ordered sent to the treasurer of the State Association.

J. M. BUFFINGTON has made arrangements at the State Board of Trade rooms, in this city, for the display of minerals from Nevada county. It is the desire to have each mine in the county represented. From ten to fifteen pounds of ore is as much as is desired from any one mine.

IT is reported that a syndicate of San Francisco capitalists are negotiating for the purchase of the Sterling mines, in Josephine Co., Oregon. This report has been circulated so often that not much dependence is placed upon it. The mine is a rich placer and is equipped for good work.

THE English company which recently bought the Iron Mountain mine, in Shasta, are surveying for a twelve-mile railroad from the mine to the S. P. track. They have not yet decided whether to work the ore there or ship to Selby, though the railroad proposition would imply the latter.

UTAH'S production of silver for the year 1894 was 6,534,182 fine ounces, of a coinage value of $8,458,200, and an actual market value of $4,114,573.40, figured with silver at an average quotation of 62.97 cents. Of gold the territory produced 54,570 fine ounces, with an actual value of $1,128,100.

THE concession granted last June for the construction of a railway in Lower California from the port of La Paz to the mining camp of El Triunfo, with a right to extend the line to Ensenada or Pescadero del Pacifico, has been declared null and void, owing to the failure of the concessionaire to deposit the required guarantee.

THE Green Mountain Gold Mining Co. has secured control of the Green Mountain cement gravel mines in Chili Gulch district, Calaveras Co., comprising about 150 acres through which run gold-bearing channels, which are to be worked to the fullest possible extent. Considerable machinery and material went with the purchase.

THE Alaska-Mexican Company reports its cleanup as follows for the month of November, 1894: Period since last return, 30 days; ore milled, 6058 tons; sulphurets treated, 137 tons; bullion from sulphurets, $4431; bullion shipped, $13,864; working expenses, $11,819; balance, $2045; average total return per ton, $2.29; expenses per ton of ore milled, $1.65.

THE Eureka Tellurium Gold Mining Company have elected the following directors: W. P. Sweezey, president; Geo. C. Jones, vice-president; J. S. Ludlum, secretary and treasurer; Anna M. Ludlum, Peter Scherer. The Redding *Democrat* says the company has an entire new process by which they will work the ore of the mine. It is a dry process.

IN the Sacramento office is being argued a suit which involves the possession of land claimed in the Mammoth and St. George quartz claims in Amador county. The question is whether it is most valuable for mineral or agricultural purposes. In any other State than California the production of gold would definitely determine the question, but 'tis different here.

GEO. W. EDWARDS, of Indiana, has bought the Spanish Hill placer mine, one mile from Placerville, El Dorado Co., and has commenced preparations for work on an extensive scale. This mine in days past was a large producer of gold, and C. W. Brewster is said to have purchased from the original locators of the claim—three in number—gold dust amounting to over $1,500,000.

A RICH vein of quartz has been struck in the La Marque mine, Nevada Co., at a depth of eighty-five feet, and the quartz taken from it is of high grade. The mine is situated in the neighborhood of the North Star and is being worked by Maltman & Thompson, who obtained a bond on the property several months ago. It is an old mine and has been worked in a small way for many years past.

THE mining share excitement in London and Paris, with shares of properties in the Witwatersrand district of South Africa as its object, says *Bradstreet's*, has had a limited but very necessary set-back. Prices for some of the low-priced shares which depended to a considerable extent upon constant puffing and advertising have had a material drop, and new issues, particularly of West Australian properties, find less favor with the public. In the opinion of the most candid observers of the situation, the movement has been overdone, and, as most of the public buying has been of an outright kind, the lockup of funds for this purpose has exhausted the available supply and caused the London mining market to assume a tired appearance.

THE property of the Oregon Gold Mining Company, at Cornucopia, Union county, Oregon, was last week sold by the sheriff, under foreclosure. The property sold includes several mines, among which is the Red Jacket, a good gold property, and a quartz mill which was built several years ago at a cost of $150,000. There were only three bidders. It was bid in by P. Basche, of Baker City, for the sum of $9000. It is understood that the bid was made on behalf of the Oregon Mining Company itself.

THE Gold Ore Treatment Co. has been organized in London, to take up commercially the matter of the new gold solvent, recently reported to have been produced experimentally by H. L. Sulman. It is a modification of the cyanide process: To a solution of potassium cyanide is added bromide of cyanogen; it is claimed with very satisfactory results. An economical process of producing the bromide of cyanogen, by which its cost need not exceed seventy cents per pound, is also reported to have been found by Mr. Sulman.

SENATOR WHITE has introduced a bill providing that in all entries of placer mines made under the provisions of the Revised Statutes by associations, or persons, or their assigns, proof of discovery of minerals on each twenty acres of land embraced by the entries shall not be required, but proofs of discovery of minerals and development thereof on any part of the entire land shall be deemed sufficient. It is provided, however, that the full amount of $500 must be expended for the development of each claim, as now required by law.

"THE Golden Star Gold Mining Company of Montana has a capital of $300,000 divided into 300,000 shares of a par value of $1 each. The company has ore in sight worth $100 to the ton, but in order to improve the property the directors have decided to put on the market a limited amount of stock which will be sold at 40 cents per share. As soon as the shaft is completed, the sale of shares at this price is to be discontinued," etc. So says the prospectus. The whole thing is a fraud, and, like other fake schemes, tends to injure legitimate mining interests.

THE case which the Commissioner of the General Land Office has decided in favor of Jno. McBride, by which he is awarded 120 acres of Section 16 of Tacoma, as a placer mineral claimant, has cost the State of Washington about $45,000, and Mr. McBride has expended about $17,000. The testimony taken occupies 8000 close type-written pages. The value of the land is estimated at from $3,000,000 to $5,000,000. The Secretary of the Interior has made the case special and it takes precedence over any actions, so that a final decision may be looked for within ninety days.

REPRESENTATIVE CAMINETTI'S resolution to suspend the patenting of land within grants to Government-aided railroads until January 1, 1896, having been unanimously reported from the Public Lands Committee, is a privileged question and can be called up at any time. Caminetti is watching his opportunity and will try to get this measure through before the close of the session. Senator White will take care of it in the Senate where the principal opponent of the resolution is, of course, Senator Stewart, of Nevada. He has already announced that he is opposed to taking this action.

LONDON men are investigating the California Water and Mining Co.'s ditch property in El Dorado county, with the idea of purchasing and developing it into a paying proposition. The Eastern owners are "conservative," and don't care to spend the necessary money to develop it. Chas. Blagburn, an English engineer who has been examining the property, believes that the expenditure of between $300,000 and $400,000 would result in business netting $75,000 or $80,000 annually. The property is a valuable one, including water rights, ditches from Loon lake, etc., and properly developed would be of value to quartz miners and fruit lands on the Georgetown divide.

RECENT local mining incorporations are the San Francisco and Cripple Creek Gold Mining Company. Principal place of business, San Francisco. Capital stock, $1,500,000, with T. N. Handy, W. K. Flint, H. A. Moss, D. E. Besecker and E. L. Ligget as directors. The Potosi Mining Company of Shasta. Principal place of business, San Francisco. Capital stock, $300,000, with F. Wieland, F. L. Ruhm, R. Klump, H. Jung and F. H. Jung as directors. The Mountain Chief Mining Company—Principal place of business, Willows, Glenn county. Capital stock, $30,000, with C. W. Grayson, Jr., C. L. Donahoe, J. F. Sersanous, W. H. Sale and J. H. Graves, all of Willows, as directors.

THE miner's bill has passed both Houses of the Legislature, and now only needs Gov. Budd's signature to be a law. It amends Sec. 1222 as follows: "The judgment and orders of the court or judge made in cases of contempt, where the contempt is committed in the immediate view and presence of the court or the judge at chambers, are final and conclusive. In all other cases of contempt the judgment and orders given or made in relation thereto are subject to review by motion for a new trial and by appeal, in the same manner in which other judgments and orders are so reviewed." That means that the hydraulic miner in this State has the same protection against arbitrary arrest that any other citizen has.

THE January cleanup of the Alaska-Treadwell shows: Shipment of bullion, $55,695; tons of ore milled, 20,491; tons of sulphurets treated, 377; of bullion there came from sulphurets, $20,405. For the six months ending Nov. 30, 1894, the working expenses were $1.38 per ton, or nearly the same as during the two previous years. This cost includes many unusual charges in connection with new machinery and with a theft of amalgam, recovery of the same and arrest of the delinquents. It is expected that, owing to new crushers, the cost of working will be further reduced. During the period under review, 122,282 tons were crushed and $307,021 realized, an average yield of $2.51 per ton as against $3.20 for the previous year. The sinking of a new shaft and the construction of new hoisting works prevented hoisting any large quantity of the higher grade ore from the 110-foot level. It is expected that from now on more ore from that level will be crushed, and that the receipts will again become equal to those of the last fiscal year. The profits for the half-year were $138,383.

Pocket Mining in California.

Written for the MINING AND SCIENTIFIC PRESS by W. H. STORMS, M. E.

The business of hunting gold pockets is a distinct branch of the mining industry in California. That, in order to be successful as a pocket hunter, one must possess a most sanguine temperament, rare perseverance and energy, and abundant self-reliance, no one who knows anything of the methods, the successes and disappointments of a pocket hunter's life will deny.

Mariposa and Tuolumne counties are the sections where pocket mining is followed more extensively than in other sections of the State, though pocket mines are not unknown elsewhere. In Calaveras county, in early days, pockets of fabulous richness were mined on Carson hill, where is situated the famous Morgan mine. This was one of the first pocket mines discovered in the State. It was located in 1850, and it is stated that from February, 1850, to December, 1851, less than two years, $2,800,000 were taken from this wonderful mine. People came from miles around to visit it, situated on the highest point of Carson hill. Robinson's ferry took in over $10,000 in six weeks as a result of the stampede. On the south slope of Carson hill a town sprang up, like a mushroom, having from 3000 to 5000 population, no trace of which remains to-day.

The Morgan mine excelled in richness anything ever found before or since. At times, so it is said, the gold occurred so abundantly in the rock that blasting was impracticable and cold chisels had to be employed to cut out the masses of yellow glisteuing metal.

The fame of the Morgan mill still clings to it, but in this age of new things it has become ancient history, and Calaveras county is no longer looked upon as a pocket mining section, though doubtless many undiscovered thousands still remain.

There are a large number of pocket mines located in Mariposa and Tuolumne counties, and some uninformed persons seem to entertain the opinion that pocket mining is exclusively engaged in in those counties. This is a mistake, however, for both of these counties have produced many millions of dollars from vein mines as distinctly different from pocket mines as those of Amador county, and there are many mines in operation there to-day employing a large number of men and producing in the aggregate much more than the pocket mines.

The Famous Bonanza Mine. — The most famous pocket mine of late years in this State is the Bonanza, at Sonora, in Tuolumne county. It is situated in the northern suburbs of the town on a smooth sloping hill.

This mine, with a record exceeding $2,000,000, is a very peculiar one, and while really not unlike other pocket mines in some important features, is nevertheless a most remarkable mine for many reasons. The pockets have ranged in value from about $4000 to over $300,000. One pocket, the largest, yielded gold weighing over 1000 pounds avoirdupois, a glitteriug mass of bright virgin gold with a considerable quantity of telluride of gold (petzite).

The total cuttings in the mine, including shafts, tunnels, wiuzes, levels, stopes, etc., are about 5000 feet. The deepest point reached in the mine is something more than 1300 feet below the croppings on the incline (about 20°).

The surface plant consists of a hoisting and pumping plant, an air compressor used to run drills, pumps and hoists underground, and a mill of two stamps. Prior to the erection of the mill about a million and a half had been obtained by using hand mortars. It has not infrequently occurred since the introduction of the mill that, when making a run, it has been necessary to hang up the stamps every hour or so to remove the gold from the battery, which had become too much loaded with the precious metal to permit further successful operation.

The value is chiefly in the metallic gold, most of which is visible to the unaided eye. Tellurides of gold and silver (petzite and sylvanite) also commonly occur. A small amount of iron sulphuret is frequently present.

It is a notable fact that the rock at a few feet, or even a few inches, from a pocket of gold, no matter how large, is entirely destitute of precious metal, merely a trace being obtainable by fire assay. The pockets ordinarily ranged from $20,000 to $50,000. I was told a few months ago that $4000 were obtained by sorting over the old dumps on Bonanza hill, where the early excavations were made. The gutter-like depression now marked by the main street of the pretty little town of Sonora, headed on Bonanza hill, and a golden harvest resulted from washing the gravel of this depression. It was this, in fact, that led to the discovery of the Bonanza mine. The method of "surfacing" for pockets will be described later.

GEOLOGY OF THE BONANZA MINE.

The Bouanza "vein," as it may be termed, though really a misnomer, is a dike of eruptive rock of light ashy-gray color, through which is disseminated greenish scales of chloritic mineral. Having never made a chemical or microscopic examination of the rock, I can only describe its physical appearance. It may be a fact worthy of note that greenish scales are found in the dikes of many rich mines of California, and in some other pocket mines. Near the surface the rock is much altered, stained with iron oxide, and banded in peculiar waving lines. It might easily be mistaken for a rotten sandstone, having a granular texture quite similar to sandstones. Specimens of this dike, both altered and fresh, may be seen in the museum of the State Mining Bureau.

The Bonanza dike is from eight to sixteen feet in thickness, striking north, 30° east, and dipping 20° to 25° north, 60° west. It cuts all the metamorphic rocks (slates, schists, limestones, etc.), and the older crystalline eruptives (diorite).

The strike of the general country rock at this place is north 30 west, with a uniform dip to the north eastward at 65° to 70°. It will be noticed that the dip of the dike is not parallel to the strike of the slates, but in a direction 30° more to the westward.

The country rock which forms the foot and hanging walls of the dike in the immediate vicinity of the pay chute are as follows, passing from west to east: a firm argillaceous rock, known among miners as "block slates:" and having a decided tendency to break up in triangular masses with smooth faces. This is succeeded by a strip of black slate four to twelve feet wide and containing an abundance of pyrite (iron sulphurets). This rock has a well-marked slaty cleavage. It is separated from the block slate by a narrow fissure, which has been persistently followed for hundreds of feet in the mine workings, the guide, as it were, to the treasure spots of this wonderful mine. This fissure is sometimes an open crevise an inch or two wide, again it contains a narrow seam of quartz, and here and there a peculiar, much decomposed material is seen which I believe to be the remains of a thin sheet of intrusive rock. A soft black mineral substance commonly occurs in the fissure. I made no test of it, though it is probably iron and mangauese. This fissure, in the language of the pocket miner, is called a "crossing," and is the strongest and best defined of a series of four fissures which occur here, having a general parallelism, and separated from each other by two to five feet of the pyritous slate. These fissures or "crossings" are usually within the limits of the pyritous slate belt.

Lying to the eastward of the pyritous slate is found a hard, dense silicious rock, having a semi-slaty structure. This rock is from twelve to twenty feet in thickness, and is succeeded by a thin strip of black slate, beyond which is found the crystalline limestone, which is a mile or more broad. It has a decided schistose structure near its contact with the clay slate.

The country rock is traversed by numerous large dikes of green rock (diorite) which have a strike usually about north, 65° east. These dikes are mostly older than the Bonanza dike which cuts them (the exception will be noted later), though sometimes appearing to be disturbed at the contact.

The Bonanza dike, as has been stated, is from eight to sixteen feet wide. Within this mass of intrusive rock there occurs, usually in the upper portion of the mine, three veins of quartz—one lying along the upper or hanging-wall side, one on or near footwall and the third in the center of the dike. The longitudinal extent of these veins has never been determined, as the workings have been confined almost exclusively to that portion of the formation along and adjacent to the four "crossings" and the black pyritous slate; therefore little is known of the Bonanza dike outside the limits of this richly spotted pay shoot, for it is a remarkable fact that the gold is found only within the limits of the pyritous slate zone, and then only along the fissures (crossings) at such points as will be explained.

In addition to the "crossings" is found another system of fissures, mere knife-blade veinlets, called "gold seams." It is at the intersection of a "crossing" and a "gold seam" that the pocket hunter hopes to find his reward, and he often does—a most substantial one. These "gold seams" lie out in the country rock—in this case, in the slates both above and below the dike. Their strike is quite uniformly 60° east of north, directly at a right angle to the strike of the slates. They all have a southeasterly pitch, but at greatly varying angles, ranging from about the plane of the horizon to nearly perpendicular. Strange to say, however, those found with an inclination of about 45°, seem to have been attended with the best results.

These "gold seams" cut down through the slates and other rocks reaching the hanging-wall side of the dike. They do not pass directly through the dike, but are usually found coursing in a more or less erratic manner on their downward trend through the dike to the footwall side, where the regular course is resumed in the slates. The gold seams within the limits of the dike are represented by narrow seams of quartz. Within the slate areas they are merely cracks.

The footwall and hanging-wall of the Bouanza dike are planes of displacement; a movement of about sixteen feet has taken place. It is a "thrust" fault, with a side throw of about equal distance—that is, sixteen feet. To make this more intelligible, we will assume the footwall slates, etc., to have remained stationary; the hanging-wall country has moved upward relatively to this footwall, a distance of sixteen feet and about the same distance to the westward, the dike simply separating the two massess. All of the rock strata, the crossings and gold seams seen in the hanging-wall country are found repeated in the footwall side, but with the displacement stated.

The pockets of gold in the Bonanza mine have always been found at the point of intersection of a "crossing" and a "gold seam," on the plane of the quartz veiu formiug the upper one of the series of three. This only obtains when the quartz was found in direct contact with the slates and not separated from them by a strip of dike material. This condition also applies to the footwall side of the dike. Some gold has been found in the central quartz vein, at the intersection of "gold seams" and "crossings," though far less than at the slate contacts. Perhaps the most remarkable feature of this wonderful mine is in the mechanical regularity with which gold pockets appear to have been distributed. I was told by Mr. Oliver, who for years superintended this mine and who knew its peculiarities well, that the pockets were found at alternate favorable points. Having found a pocket at the proper intersection of seams and crossings, etc., the next crossing would apparently have all the requisite conditions while no gold was found, but the next would be found to be the nucleus of a pocket. This peculiar fact has never been accounted for satisfactorily. The miners were satisfied to find a pocket, and they didn't trouble themselves about how it came there.

In the lower levels of the mine the three quartz veins found in the dike above appear to have united and formed a single vein two to four feet thick near the center of the dike, being separated from the slates above and below by six to ten feet of dike material, and, as a consequence, pockets of late have been both few and small.

The country rock has been greatly disturbed by the intrusion of a number of large diorite dikes, one of which is evidently younger than the Bonanza dike. The hope has been that by sinking deeper this disturbed region may be passed and that the same conditions found above may be discovered beyond with the rich deposits of gold.

Telephones for Mining.

Many difficulties attach to the use of the telephone in mining operations, not the least of which is the liability of the wires to be broken by falling rock or shattered in blasts. The apparatus itself is also attacked by many troubles peculiar to the situation. Yet the advantages of telephonic communication in a mine are numerous, and the service is now frequently resorted to. In the telephone sets thus used as little metal as possible is employed, and that little is carefully protected from exposure to the air. It has been found that for a set to be used in a mine, wood is the best material. It is creosoted and thoroughly covered with a waterproof paint. As far as possible all joints are dovetailed, or elaborately packed. As it is necessary to have the gongs for the bells on the outside of the box, as well as the handle of the magneto generator, the familiar crank and the little hammer between the bells enter the box through glands that are water-tight. The transmitter and receiver are also cooped up within the box, and connected with the outside by means of long flexible tubes, the interiors of which are of metal. It has been found that in this way the moisture is condensed on the sides of the long tubes, and little or none on the diaphragms. If exposed, the iron diaphragms would last but a few weeks; as it is, they have been made in this way to last an indefinite time.

Prospecting Enterprises in Nevada.

Some of our people, says Dan De Quille, are talking of striking out into the central and eastern parts of the State in April or May to prospect for gold. They will not look for or try to do anything with silver-bearing veins, unless they find pure metal on the surface. The miners who have small gold veins in the vicinity of Hawthorn, Silver Star and other gold-bearing sections are "making a live of it," and that is more than men are doing here who cannot get a place in one of the mines. It is seen that those of our people who go to these little gold camps seldom come back to the Comstock. As soon as they become acquainted with the nature of the veins they get a hold somewhere and stay. In all the gold belts where paying mines have been found there is a chance of finding other veins that will pay; besides, there are vast tracts of country that still remain to be explored. In many sections where there are mountains there are metals of some kind. This State offers a fine gold field for prospectors. There are probably veins here rich in gold that our prospectors would hardly look at. We here know nothing about any "gold ores," and pay no attention to any kind of quartz that does not show "free gold." There are probably ores here in many places that would pay well if worked by the new processes now being used.

"Some Mining Experts."

"What fools we mortals be."

To THE EDITOR:—Nature has shown what may be done under favorable climatic conditions in this far-western country of ours, not alone in the vegetable and animal kingdom, in forests unequaled elsewhere for individual growth and numeral extent, citrus fruits and garden truck, fast horses and handsome women, but another most prolific crop, not wholly indigenous to the soil, has not received the recognition due its attainments and unworth. This is the abundant herd of home-made, self-appointed "mining experts," who, within a few short months or years, without study or practice in school or field, are possessed of a depth of learning and a knack of reading the "great stone book of nature," truly marvelous to less gifted lifetime plodders in the mineral world.

Not alone is the layman in mining affairs, who is looking for an investment of his surplus coin, taken in, for the shrewdest of men, having no knowledge of mining, may be persuaded by the suave bearing and stock technicalites of the operator, but the profound indifference—to call it kindly—with which the mining public have acquired the faculty of absorbing any and all kinds of traveling "mining experts" passes belief. Given a high per cent of gall, an agreeable presence and conversational power—the stock in trade—they just drop in on a mining community either to expert (?) a mine or something with dollars in view, do a judicious amount of chin work and the native is captured. Now, to a tree-roosting Zaccheus, this is all very amusing and refreshing, but it becomes most monotonous when these people again and again—knowing they have been "done up"—keep on "kissing the rod." I doubt if a single mining camp of the West can claim freedom from this charge. Strange, isn't it, this Jonah's gourd variety of experts never gravitate to or care to know the leading mine superintendents or reputable mining men of known standing in a community, rather airing themselves on other subjects, barely touching on mining, with a half-concealed, half-revealed reserve of information that seldom fails to complete the capture of the unsophisticated listener in hotels and bar-rooms. Several known to the writer have acquired lungs and mining lore in this most delectable clime, possessing neither of moment when they got here.

The most delicious part of the whole affair is the bland affability of these ex-Counts, bee-herders, barkeepers, and what not, toward their admiring constituency and generally lack-luster-mentally admirers. The subject is very provocative of sarcasm and ridicule, hurtful as it is to legitimate mining, but where's the use; the general public may or might appreciate such a straying from the trail of mine correspondence, yet those for whom it is intended would smilingly and kindly pat themselves on the back and thank their precious God, "They were not as other men!" and apply it to the other fellow. Hence the casual reader will appreciate the difficulties under which the writer labors.

From where come these warts on the face of the mining industry, neither ornamental nor useful? All fields of business and grades of idleness are represented, though they are largely recruited from the whisky men; barkeepers probably have the first call. Generally the only public resort in a mining camp is the saloon. It is there men bring their ore samples to show improvement in development or talk over some new find. The "barkeep"—"fly" fellows as a rule, chronically opposed to manual labor—naturally gleans considerable information of the local conditions of ore deposits. He, if any one, sees through the veneer of the galvanized, itinerant mining expert, with the natural inference: "If that fellow is an expert I'll just try it a jolt myself." So he hies himself to some distant point and proclaims himself, and with his knowledge of human nature, acquired in "setting 'em up," and control of nerve and countenance in "standing pat on a four-card flush," he is apt to make it win.

A close second are store clerks from mining camps. What affinity there is between soap and sugar and the science of mining is beyond my feeble ken. Yet it must exist, else why so many graduates from behind the counter. Due credit should be given to the large contingent reaching from the saw-log expert of the Puget Sound to the bee vaquero and alfalfa brother of California and Arizona. The majority of this latter constituency simply mine-expert as a pastime, as a sort of lesser side issue to herding the festive bee or wrestling with the alfalfa or rutabaga problem.

Let us not forget the "Broker" and "Mine Promoter." These are slick talkers to people not familiar with mining. The "Counts" and "Dukes" of kindly advice (for coin of the realm), with a goodly (no pun) quota of ex-parsons, who certainly, having full power to down the devil, are qualified to best any earthly foe. They rank as generals, colonels and majors, never a lower rank, with a scattering of professors.

Now, many of these are bawling, noisy creatures, the loud-voiced recitals of their mining exploits, conveniently in some distant field, are in continual evidence. The whole matter of talk revolves around one central nucleus, i. e., the first personal pronoun. They toot their horn with a vim and continuity flattering to the lung-building power of our ozone-charged atmosphere. And, do you know, this brazen mouthing is really convincing to some otherwise sane people. Again others do the whispering act. They are the most dangerous, for, keeping their mouths shut and looking wise, they gather all the information possible in camp and build their reports thereon. All work any secret orders they may be members of for all that is in them, and it is a very strong card, you may be assured.

It would be well not to refer to the civil engineers, who think, because they are familiar with the working of a surveying instrument, they are thereby qualified to write themselves "mining engineers."

A civil engineer is no more a mining engineer than an ordinary engine driver is a machinist. A mining engineer, or "expert," presupposes an intimate knowledge, in the field, of mineralogy and mining geology, the method of attacking and actual development of any class of mines, a further practical acquaintance with mining chemistry, in fact, from underground surveying, the assaying and analysis of ores, to the brittling or tempering of drill or pick, and the placing of any or all mine timbers.

For this, a wide and practical field knowledge, added to thorough and constant study in books and leading mining journals, to keep abreast of the improvements and experiences of others, is essential.

In view of these varieties, and granting there are bright men interested in legitimate mining, grown gray in the service, who are often in doubt and hesitate to pass on the value of a mine, does it appear reasonable that others, having but a superficial knowledge of the business, probably acquired as manager, should be able to read the riddle of a mining proposition's future, if indeed of its present value. The following quotation is true to the letter: "There are belts and lodes of mineral in the earth that have certain limit, sure and certain manner of occurrence and regular deposition. Here the mineralogist and geologist step in and define them, toiling away until the rocks tell their own story of hidden treasure. By deductions the geologist locates mineral belts, natural gas, oil, marble and minerals." It is not to be forgotten that his theories have to be tried in the crucible of experience. Mining is expensive at best, and where wise, careful and competent advice is not had the chances are all in favor of failure and consequent harm to an entire community. Particularly is this incompetent advice disastrous in the inception of a mining enterprise in an untried field, where the highest degree of efficiency and experience is required. Just one bad break in a struggling young camp and its growth is retarded for years, if not damned eternally. In support of this assertion I refer the reader to his own or his neighbor's experience, if a miner.

TAYLOR D. MACLEOD.

Yuma, Arizona, Feb. 23d, '95.

An Old-Time Mine Hoisting Apparatus.

The man engine, familiar enough to underground miners of a generation or two ago, is fast becoming a relic, and many engineers there are to-day who have never seen one, nor even an illustration of one. With but few exceptions, in fact, at the famous Calumet and Hecla mines in the United States, for example, and in some of the old European mining districts, the man engine has long since been abandoned for the modern hoisting plant, and the experience of ascending or descending a mine shaft, platform by platform, or the steadily up and down going rods of the old-fashion apparatus, is one for which all opportunity will soon have gone. To the many who do not know the man engine, even by name, it may be interesting to be told that it consists of little more than a rod, vertical generally, though sometimes inclined, depending upon the run of the shaft, extending from the surface to the bottom of the mine, and moved up and down like a pump rod by means of a steam engine or a water wheel. The length of travel of the rod commonly adopted is twelve feet, and at intervals, equal to the length of the stroke, small platforms are fastened to the rod, while corresponding platforms are fixed to the walls of the shaft on either side of the rod, and at points correspounding to the limits of the stroke, both up and down.

A miner in descending, say, steps on a platform on the rod just as the down stroke begins, and steps off onto the platform in the shaft which he reaches at the lower end of the stroke, repeating the operation till he reaches his destination. In ascending, similarly, a miner steps onto a platform on the rod as the upward stroke begins and leaves it at the end of the stroke. Ascent and descent, as will readily be understood, may proceed simultaneously without interruption, the fixed platform on one side of the shaft being reserved for the men ascending, and those on the other side for the men descending, each man stepping on his proper platform on the reciprocating rod as it is vacated, at the moment of rest between the strokes, by the men going in the opposite direction. This form of single-rod man engine is even now in use in Cornwall, and in Scotland. In the Harz mines, in Germany, the birthplace of the man engine, the double-rod engine is in use, the two rods moving up and down alternately, in opposite directions, and, accordingly, carrying the men at twice the speed that can be attained with the single-rod kind. The apparatus corresponds practically to a ladder with movable steps, the miner having nothing to do but to move slightly sidewise in order to place himself on the step about to go up or down, according as he wishes to ascend or descend. Cassier's Magazine.

"Reporting on Mines," Etc.

To THE EDITOR: Discussing this subject in a recent issue of the MINING AND SCIENTIFIC PRESS, Mr. E. F. Schaeffle has a good word to say for the ordinary miner's report, while slightly reflecting on the more elaborate ones made by experts. Personally, I have very little use for the latter, but it does not follow that the average miner is a luminary on the subject of his own mine. Put an advertisement in a paper for a mine and see what descriptions you will receive from owners.

Most of them will consist of a few lines on a page or two of note paper, giving no information whatever, and asking you to "come and see for yourself." Mr. Schaeffle says, truthfully: The average buyer requires the "location of a mine; its situation as to roads and water power; the character of the ore; average width of the vein; length of the 'shoot,' with sketch showing developments; average sample of the vein, etc." If he has succeeded in getting these few simple requirements from owners, he has been more fortunate than I have ever been. One would think that a man living on his property for years should be able to enlighten you on these points, but my experience has been that he is not. In many cases I admit he has good reason not to tell the exact truth, but much of his reticence is also due to innocent ignorance. One who has been about mines much knows well how infatuated some owners become with their properties. I know of a case where a miner has been at work for nineteen years on a tunnel which he has driven in nearly 1000 feet on a broken or almost barren vein. Some time ago I visited a mine whose owner made a boast that it had been condemned by ten experts. I carefully sampled the twenty-nine-foot vein, with the assistance of that very owner, and found that the ore did not go seventy-five cents to the ton, and I have no doubt that the said owner has ever since been considering me as big a fool as the others.

The ordinary miner, even when acting in good faith, does not happen to be an authority on the quality of his own mine; but, unfortunately, his more intelligent and successful brother is hardly more satisfactory in this respect. If you ask the owner of a producing mine for data concerning his property, he will often demand a large sum of money to be put up as a forfeit before he will even talk. This is foolish. There are mine owners and mine buyers; these are thousands of miles apart, as a rule, and have rarely heard of one another. A party chances to be in California who might be the missing link between the two. He hears of a certain mine with a big (newspaper) reputation, and thinks it might be acceptable to certain bankers or syndicates he knows in New York and London. He applies to the owner in the way of business, and he is told to put up a deposit if he wants to negotiate. Why should be put up money on something he does not know anything about? People do not want a mine until they know what it is, and how can they know what it is unless the owner gives them the information or permits an expert's examination? Owners seem to think a mine is bought like a horse or a pair of blankets.

This is never the case in operations on a large scale, at least. There is no one single man who is ready to pay $500,000 or $1,000,000 for a mine. A large mine is always taken by companies, and to organize companies requires months of hard work, high financial influence, and a vast outlay of diplomatic skill. The usual history of a successful mining deal is something that people here know very little about, and is simply this: A promoter, middleman, or whatever you choose to call him, gets a report and an option (generally from sixty to ninety days) on a mine, and sends the proposition to his syndicate in the East or abroad. These proceed to expert the property and, if all right, make a partial payment for an extension of time, and then begin to work up a deal which will cost them from $25,000 to $75,000 before they get through. If it is not a "go," they are out this sum; and it is the expense that must be incurred in every venture of this character that makes it so difficult to get mines considered by capitalists.

There are no exceptions to this rule. The Josephine, the Union, the Ilex, the Valley Gold, the Sierra Buttes, and recently the Elkhorn, the De Lamar and Harqua Hala were all sold in this manner. It is amusing to read in the newspapers or to hear owners talk of the million or two millions they have been just offered outright for their properties and which they "refused," of course.

Mr. Schaeffle has done well to moot this topic, for it is one concerning which there is a great deal to be learned by miners, both obscure and conspicuous—especially the latter. ALPHA.

Men Whose Labor is Slowly Fatal.

That the conditions surrounding some of the trades knowu as unhealthy or dangerous have been mitigated by the appliances of science, is an undoubted fact. Still these cases are few, and in many instances, through the cupidity of employers, the safeguards which science has provided is neglected. Very often the workers themselves are the victims of their own recklessness.

Of the trades which tend to shorten life, the polishing and grinding trades have probably the most victims. Formerly the mortality of people who used to work in the needle factories was so great that special legislation had to be invoked.

The wages of these people were considered high. In fact, people are tempted hy high wages to engage in them, with a full knowledge that their span of life would be shortened.

The whirring, grinding machinery filled the air with metallic dust, which entered the lungs, no matter what precautions were taken. All kiuds of guards were tried and proved failures, until a frame-work of magnets to fit around the mouth and nostrils of the workers was invented.

This attracted the metallic particles aud ohviated the evil. The apparatus has been improved and modified until the trade is a fairly healthy one.

Brass workers are suhject to the same evil, but not to the same extent. Steel or iron being shorter in "grain" than hrass, sends more minute and impalpahle clouds of dust in the air when ground than brass. Magnets, however, will not attract brass dust, so that brass workers are short lived. In emery factories, where there is a constaut cloud of emery dust, various plans have been adopted to prevent the dust from entering the lungs. Noue of them has proved more than partially successful.

Knife and scissors grinders live short lives. Even if appliances are provided to reduce to a minimum the quantity of dust which euters their lungs, the workers grow careless themselves, just as people who are accustomed to walk on high scaffoldings become reckless and fall victims to carelessness.

Stone cutting and stone polishing, when the latter is dry polishing, comes under the head of the dangerous trades. Though not as bad as knife or scissors grinding, still particles of the stone dust find their way into the lungs, which means consumption sooner or later.

The trades connected with the mauufacture of chemicals. paiuts, the use of paints and the grinding of colors carry thousands of victims away every year. A labor leader who has given years to the suhject of these trades, says: "Few people can realize the enormous number of deaths all over the world of people engaged in just such trades. No statistics that were ever collected could do justice to the fact. Why do they choose such trades? you ask. All I can say is that 'all men think all men mortal but themselves.'

"In some of these trades the wages are not even tempting, but people have an idea that they will he all right. All lead trades are bad; they poison the blood, but some people are more susceptible to lead poisoning than others. Printers all know what 'printer's colic' is, coming from handling the type.

"I have known of men particularly susceptible to lead poisoniug who have been paralyzed in one or both arms from handling types. This is not a very commou case however.

"Minerals which are liquid or semi-liquid are the worst," he continued. "They are breathed and taken into the lungs and carried through the blood. Arsenical paints, through their vapor, find their way iuto the lungs and stomach. The wearing of wet sponges before the mouth and nose somewhat ohviates this."

One of the most terrible trades in its effects is the making of matches, or work in which phosphorus and sulphur are used. Efforts have been made to render it less dangerous, but science can do little, though the increased use of machinery has rendered the evil less than it was. A man seen on the subject, who was once superintendent of a match factory, said the fumes of the phosphorus act on the teeth and jaws so that the teeth loosen and fall out. Then the jaw swells and the gums dry up. The hones of the jaw become hrittle, and at last the bones hegin to drop out iu pieces. Occasionally the skin swells and the bones drop out through the skin. Some can stand it better than others.

Asked if there was any safeguard, he said: "The ouly safeguard is care. It is a dangerous trade, but people can make it less dangerous by avoiding the inhalation of the fumes. Some people used to die in five years, but more care is taken now."

Another trade which used to carry off many victims is glass hlowing. Glass blowers inhale hot air, which gradually wears away the delicate mucous covering of the throat and lungs and death ensues.

Dye works also contribute their quota of victims from lives shortened by inhaling chemicals.

It might he asked how it is that so mauy healthy people can he found in these callings. The answer is that there are people who are less susceptible to such poisoning than others.

Recklessness is the great destroyer of life. A little common sense makes some dangerous trades measurably safe, and the want of it increases the danger.

In the building trades the housesmiths take the greater risks. There is nothing in the work to necessarily shorten life except that accidents occur, but they are so frequent that the trade is dangerous.

Any one who looks up at the iron skeletons of any of our great sky-scraping buildings in process of construction can realize this. Men ou giddy heights are stepping from beam to beam when a single false step would mean iustant death. So slight is the balance sometimes that a sudden gust of wind or a wet, slippery spot trodden would cause a worker to lose his balance, and a terrible death is his fate.

The list could be lengthened indefinitely. In nearly all trades which could be called dangerous independently of those which would be called uuhealthy, the habits of the worker have a good deal to do with his chance of longevity.

Carelessness and recklessuess have caused more deaths thau all the primary causes combined in the dangerous and unhealthy diseases named.

About Gold Mining.

A Deuver mining mau, in a letter to an Easteru paper, makes a few pertinent remarks on the business of gold mining in his State, which applies in general. In giving emphasis to his statement that success in legitimate mining depends as much, if not more, on business ability than science, he says:

Occasionally there will be met with a rich gold mine which will stand for a brief period that kiud of reckless and extravagaut management that would send the chills down the back of a conservative Boston business man. These mines are few and far between, but their very existence does more harm than good from the fact that the methods applied in their management are also tried on other properties, which, while possessing large wealth in gold, are not of such a nature as to stand this kind of "kid glove and champagne" management, and hence the enterprise invariahly ends disastrously, and a valuable miue is abandoned as worthless.

All over the western mining country there are old gold mines with millions of dollars in low-grade ores, which were abandoned years ago at the time the silver excitement spread its allurements to the miner. At the present time our conservative and wide-awake mining men are quietly securing control of such properties as these. They are equipping them with moderu plants of machinery and erecting works for the reduction of their ores by the proccss or processes which have proven to he the most adaptable to the husiness of extracting gold from just that class of ores.

They are not earning fabulous dividends nor are they losing anything, but they are earning those dividends which could reasonably he expected from any legitimate manufacturing enterprise. This is mining and business combined—the kind of mining that furnishes employment for competent mine superintendeuts, business men and metallurgists, who take large interest in their work of producing gold for Uncle Sam without question of loss or chance. In this kind of mining you will not find the speculator or expert.

So now if your Boston or New York capitalists want to make miniug investments, not speculations, go to the experienced western mining man, tell him what you have to invest, and above all, impress ou him the fact that you have no money for speculation, but wish to engage in some legitimate enterprise as a business venture with as little of that element "chance" to enter into the transaction as is possible. If your mining mau (don't call him "expert," the name applies too much that is not complimentary in this western country) understauds his busiuess he will get you a mine with ore in it, hut probahly of such low grade that it will take considerahle money to place it on a paying basis. There are hundreds of such mines in the West whose owners know the value of their properties, but are too poor to work them themselves, and seldom find an opportunity to sell, for the majority of buyers are speculators only and are frightened away by the preliminary outlay necessary to "open up" the mine. When you have your mine in view it is no difficult matter to estimate its real value, the amount to he expended for development and the value of the ore bodies, working, costs, etc.

The only actual risk run is the sudden "playing out" of the ores in the mine, due to more or less geological peculiarities for which our Creator is alone responsible.

THE register and receiver of the Redding Land Office puhlish a notice to miners that the C. & O. R. R. intends applying for patents to the SE¼ of section 3, and all of section 11, in towuship 33 north, range 7 west, and S½ of NE¼, section 1, township 32 north, range 8 west. Parties interested have 60 days in which to protest. It's only a little matter of a million acres. The California Miners' Association will file a protest this week.

Protecting Mineral Lands.

Earnest effort on the part of the Committee to Protect Mineral Lauds, appointed at the recent convention of the California State Miners' Association, has checked the process of wholesale transfer of mineral land to the railway companies. The latest attempted grab is reported from Redding, where about 1,000,000 acres are involved. The committee is hard at work, and their lahor is for the public good in preserving the public domain from unjust absorption. The following address is issued, which tersely sets forth the facts:

To the People of California:—The efforts of the California Miners' Association to protect the mineral land within the railroad grants in this State from heing patented as agricultural lands under the rules of the Department of the Interior, dated July 9, 1894, require the expenditure of large sums of money. Maps intended to show graphically the relative position of mineral belts, mineral entries and locations and the railroad lands are heing prepared. An agent of the Association is employed at Washington to further its interests and to secure favorable action in Congress and the Land Department in the matter of the preservation of the mineral lands to the miner and the prospector. The Committee on the Protection of the Mineral Lands is compelled to gather about it a corps of assistants, which must be paid for its services.

So far this committee has filed, or is about to file, protests against railroad selections in this State involving more than 1,500,000 acres of land, all not necessarily mineral, hut all of which, in the absence of protest, would he patented to the railroad companies as agricultural land, irrespective of their true character and the possessory rights of mineral claimants thereto. Hearings to determine the issues raised by these protests will shortly he ordered in the respective land offices wherever such lands may be situate, and unless such protests are supported by proof made at the proper time, the whole matter will go by default, and title to these lands pass to the railroad companies.

The orderly presentation of the cases will demand considerable outlay of money; it can be obtained only by voluntary subscriptions, and the California Miners' Association now appeals to the people of California to give it substantial pecuniary aid in maintaining this, the first systematic and effective effort to protect the mineral lands within this State for the uses of the prospector and the miner.

The Association does not seek to deprive any railroad company of any lands granted to it, hut it denies that mineral lands are included in such grants, or that the Department of the Interior can properly promulgate rules to arbitrarily determine the character of lands lying therein, and by so doing abrogated the laws of Congress and the decisions of the courts. But mere denial is one thing; to substantiate these rights is quite another thing. For the latter the money is needed. To the end, therefore, that full justice may be done in the premises, the California Miners' Association respectfully asks for contributions to this cause.

San Francisco, March 1, 1895. A. H. RICKETTS,
Cbairman of the Committee on the Protection of the Mineral Lands, California Miners' Association.

The PRESS has had so much to say about this matter that it can only reiterate the manifest necessity for the present movement and urge immediate and substantial response to the above appeal. This is no charity matter. Miners' rights, the public good, are endaugered; it is for miners and the public generally to supply with the sinews of war those who are making the fight. If they fail it is the public's loss. To he successful they must have money, not for salaries or fees, hut necessary expenses incurred.

Personal.

PATRICK KERVIN bas gone to Sonora, Mexico, to examine some gold properties for JNO. W. Mackay.

S. S. BURT, a Chicago man who has been looking for South American gold mines, is in the city with alleged desire to huy a California gold mine for some capitalists of his city.

DOCTOR THOMAS ADDISON, manager of the General Electric Company, sailed for Honolulu on the 13th ult. for a brief business trip. He is expected back the first part of next month.

CAPTAIN ALEX. THOMPSON has purchased tbe Alaska *News*, published at Juneau, of W. H. Carpenter. Mr. Carpenter has the gold fever and will soon go up tbe Yukon river in scarch of the yellow metal.

THE Bigsby medal has been presented to Prof. C. D. Walcott, Director of the United States Geological Survey, hy the London Geological Society for his valuable contributions to geology and paleontology.

JOS. CLARK, who recently resigned the superintendency of tbe Poorman mine, has taken charge of his brothers' property at Trail Creek. The Le Roi Mining Company, at Trail Creek, has secured the services as superintendent of Geo. Bent, recently in charge of the Bunker Hill and Sullivan mines at Wardner, Idaho.

Obituary.

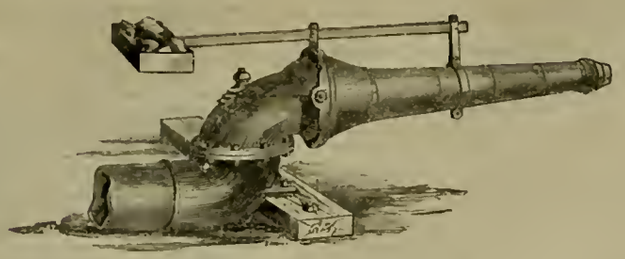
H. A. ADAMS, a native of Grass Valley, and a well-known California miner, died Jan. 25 at Johanneshurg, South Africa, where he had for some time been resident accountant at the Simmer and Jack mine.

Book Review.

SCIENTIFIC LECTURES, by Ernst Mach, Professor of Physics in the University of Prague; translated by Thos. J. McCormack. The Open Court Puhlishing Co., Chicago.

The "popular science" idea does not receive customary recognition in this book of 300 pages. Yet those who seek popular science, which is simply organized knowledge simply set forth, could find much to interest and instruct in this admirable translation of twelve fine lectures on sundry scientific subjects. Two of the twelve—The Conservation of Energy, and, On Transformation and Adaptation in Scientific Thought—are good examples of abstract reasoning, of surprising originality. Such subjects as "Why Has Man Two Eyes?" "The Velocity of Light," and "The Fibres of Corti," clearly and pleasantly discuss more concrete phenomena. The hook is worthy a place in any scientific library, and the translator deserves a word of praise for his idiomatic skill in rendering the German expression into our English form of speech.

IMPROVED FORM OF HYDRAULIC GIANTS.



The above cut illustrates the IMPROVED FORM OF DOUBLE-JOINTED HYDRAULIC GIANTS which we manufacture, and which are pronounced far superior to the SINGLE-JOINTED style. The latter, however, we furnish when requested. Prices, Discounts and Catalogues of our specialties of Hydraulic Mining Machinery sent upon application.

JOSHUA HENDY MACHINE WORKS, 42 Fremont St., San Francisco.

METAL MINING

Mechanics; Mechanical Drawing; Electricity; Architecture; Architectural Drawing and Designing; Masonry; Carpentry and Joinery; Ornamental and Structural Iron Work; Steam Engineering (Stationary, Locomotive or Marine); Railroad Engineering; Bridge Engineering; Municipal Engineering; Plumbing and Heating; Coal Mining; Prospecting, and the English Branches. A blowpipe outfit and case of mineral specimens *free* to students. Send for Free Circular, stating the subject you wish to study, to

The Gates Ore and Rock Breaker

Gives a finer product than any other crusher made, adding by this means 25 to 30% to the output of any mill, beside saving the wear of the more costly machinery. It will reduce a given amount of ore at one-third the cost in wear of any other crusher on the market. It requires also much less power for the same amount of work.

The Gates Ore Crusher

Is now being adopted by the progressive Mining Companies in all parts of the world. More than 3000 of them now running.

The Pelton Water Wheel Company, General Western Agents,

121 Main Street, San Francisco, Cal.

MINE BELL SIGNALS.

Adopted, Used and In Force in Accordance with State Law.

FOR THE CONVENIENCE OF OUR READERS IN THE MINING COUNTIES WE PRINT IN LEGAL SIZE, 12 X 36 INCHES, THE MINE BELL SIGNALS AND RULES PROVIDED FOR IN the Voorhies Act, passed by the State Legislature and approved March 8, 1893. The law is entitled "An Act to Establish a Uniform System of Mine Bell Signals to Be Used in All Mines Operated in the State of California, for the Protection of Miners." We can furnish these Signals and Rules, printed on cloth so as to withstand dampness, for 50 cents a copy. MINING AND SCIENTIFIC PRESS, 220 Market Street, San Francisco, Cal.

The Mineral Hydrocarbons.

Their History, Geography, Geology, Physical and Chemical Properties and Uses.

NUMBER XXIII.

Written for the MINING AND SCIENTIFIC PRESS and copyrighted 1894, by Henry G. Hanks, F. G. S.

Natural gas in California was known to the Indians before the coming of the whites. The gas spring at Sulphur Creek, Colusa county, aud a similar one in Mendocino couuty burued at intervals, lighted by accident from their fires, and continued to flame until another accident extinguished them. It is not known that the Iudians regarded this natural phenomenon with superstitious or religious interest.

The first account of inflammable gas below the earth's surface in Califoruia, I have found recorded, dates back to 1872. It states that a man named Cook was working in a mining shaft near Sutter City, Sutter county, prospecting for coal. A blow from his pick was followed by a flow of gas, which, igniting from his candle, exploded with great violence. The shaft was filled with flame, which rose to the surface of the ground. The windlass was blowu away and Cook was with great difficulty rescued by his mates. (Marysville *Appeal*, quoted by the MINING AND SCIENTIFIC PRESS.)

Emanations of natural gas are common in California. Those most frequently met with are carbonic acid, hydrosulphuric acid and carburetted hydrogen. The first is abundaut in the solfataric regions, and is generally associated with ores of mercury. Hydrocarbous are also found in some form in nearly all kuown quicksilver mines. In California their preseuce interferes very materially with the metallurgy of mercury. Being volatile like that metal, they sublime with it and are found difficult to separate. During the first workings of the great "sulphur bauk" near Clear Lake, the greatest difficulty eucountered iu refining was the presence of mercury, which blackened the sulphur when attempts were made to purify it.

Owing to the solfataric energy the heat in some of the Califoruia quicksilver mines is oppressive, aud the gases generated are daugerous. Raynal has called attention to the same peculiarity in the Idria mine in Australia. "There are places where it is so hot that if one stops ever so short a time one is in a profuse sweat. It is from these subterraneau caverns that mercury is drawn." (History of Settlements and Trade in the East and West Iudies, vol. II, fol. 540.)

Carbonic acid gas is so abundaut in some of the quicksilver mines iu California, notably in Napa, Lake and Sonoma counties, that exhaust apparatus is employed to clear the galleries and shafts so that the miners can work. Small animals have been known to die from the effects of this gas overflowing from the shafts of the miues. Bubbling gas may be noticed in the beds of streams aud shallow basins of water. It no doubt escapes in the same manuer on the dry land but is not uoticed. Over the entire surface of Clear Lake bubbles of rising gas may be seen, aud the great gas fountaiu at Soda Bay causes the water to boil like a cauldrou. This gas, without proof, has been assumed to be carbonic acid, which most likely it is, but it may be carburetted hydrogen or illuminating gas.

There can be uo doubt that the agencies which have produced older deposits of mercury are still iu active operation here. In Pope valley, Napa county, a small stream passes very close to old workings; aud in shallow pools, caused by slight obstructions in the bed of the stream, the bubbling of gases may at any time be seen. This locality has recently gaiued quite a celebrity as a source of a valuable mineral watcr, and the shaft of the old "Valley quicksilver mine" is now the "Etna springs." I have frequently been many feet below the level of the present surface of this now well-known mineral spring.

There are about one hundred known mineral springs in California to which more or less attention has been drawn. All are engaged in geological and chemical work. The peculiar conditions under which they exist give them the character which distiuguishes them from others, and the waters always hold in solution a large perceutage of mineral constitueuts, some of which are made more solublc by the presence of absorbed gases. They are frequently saturated and sometimes supersaturated. At one point in their passage through earthy strata they take part in the decomposition of older rocks, a portion of which they convey in solution, and deposit minerals of a different character at another far distant. The labor of this active agent is seldom realized even by the practical geologist, much less by the casual observer. Not only do these waters deposit vast quantities of distinctive minerals, but they furnish cement to form elastic rocks, which are thus changed from loose fragments and sediments to solid rock masscs.

There is a mineral spriug two miles south of Salmon creek, iu Monterey county, which is sour. It is said to be the custom of those who reside uear to add sugar to the water and drink it as lemonade. A mineral spring on township 24 south, range 5 east, in the same county is called "the Devil's spring" and "the Poison spring"—the latter because small auimals are frequently found dead on its margin. It has beeu discovered that the water is not really noxious, but that animals die from inhaling carbonic acid gas, which is evolved in large quantities. This is illustrated by an experiment frequently made. A large bundle of dry wild-oat straw is iguited, and, while burning fiercely, is held over the spring, when it is immediately extinguished. Like most of the mineral springs iu California, this one is near a quicksilver mine, and is itself au active solfatara.

There is said to be a poison spring in Mendocino county, which is described in a recent newspaper article, from which I quote without responsibility for its truth.

"The spring is situated about three miles from Hoplaud in a clump of stunted trees. The water is clear and colorless and makes a hissiug noise as it issues from the ground. The bodies of many small animals lie near its margin. There rises constantly from the spring a gas so noxious and deadly that one whiff is sufficient to extinguish life. On one occasiou a girl of six years wandered from home aud was found dead at the spring with the dead body of a bird in her hand. She had probably seen the bird at the margin of the spriug, and, stooping to pick it up, had beeu overcome by the gas. There is also a story of an Indian squaw who lost her life while stoopiug to drink the waters. The writer complaius that there is no fence built aronnd the spring or warning notice posted."

It is generally assumed by chemists that all carbouic acid has at one time been combined chemically with other elements or compounds, aud that it is the result of this that those eternal changes are continually taking place in nature to which all life aud energy are due. It has been set free, in the languagc of the chemist. Whether this is uuiversally the case or uot, it cannot be doubted that when it escapes from the surface, as it does iu California, it results from decomposition of minerals in subterrauean rocks.

Issues of carbonic acid gas are common iu the vicinity of volcanoes, aud where volcanic rocks exist it is supposed (perhaps erroneously) to be the result of the remains of extinct volcanoes. Grotto del Cane, near Naples, is a noted example.

This is a small cavern between Naples and Pozzuoli, iu Italy. It is so named because if a small dog is brought in he soon becomes insensible, but soon recovers on being takeu without delay into the fresh air, or deluged with water. The grotto in artificial, having been excavated in mining for pozzuolana. It is only twelve feet in length and four or five feet wide. An average man can stand in it without bending; the lavas forming its walls are compact, of a dark gray color; they are somewhat magnetic.

The grotto lies near Lago d'Agnano; it probably existed in Pliny's time. The waters of this lake were formerly agitated by emanations of bubbliug gases, but this had ceased in 1788; near by were the "stoves of St. Germauo" and the ruins of bathing houses, with tubes of terra cotta for couveying hot water and hydro-sulphuric acid gas, called "hepatic vapors," still in place. The mephistis in the grotto of Del Cane is so mixed with atmospheric air that phosphorus and gunpowder burned in it, as proved by Breislak's experiments in 1788. Spallanzani came to the conclusion that the carbonic acid was generated by the action of volcanic heat on decomposing lime rocks below the surface.

That author and traveler also visited the grotto iu 1788; in 1790 Abbe Breislak sent him a communication, which, quoted in full in the first volume of his travels, recites a series of experiments made in the grotto. The depth of the gas (called by him also "mephistis") on the floor of the cavern was found to be eight Paris inches. He also convinced himself that the gas was carbonic acid gas mixed with atmospheric air.—(Travels in the Two Sicilies, Vol. I, fol. 90.)

Daubeny thus refers to the nature of the emanations in Grotto del Cane: "The sensation I experieuced in stooping my head for a moment to the bottom resembled that of which we are sometimes sensible on drinking a large glass of soda water in a brisk state of effervescence; the cause of which in both cases is plainly the same."—(Descriptiou of Active aud Extinct Volcanoes, fol. 173.)

Grotto del Cane is specially interesting only because it was the first example known, and because it has been so often described and referred to in history. The conditions found in Italy are not rare, but exist in numerous places in other parts of the world, including California.

There is an engraving of Grotto del Cane in "Observations Upon the Antiquities of Herculaneum," by M. Bellicard, 1753, planche 27, and also a full description ou folio 122 of the same work.

(To be continued.)

SISKIYOU

QUARTZ AND PLACER

Gold Mines.

Parties desiring to invest in paying quartz or placer gold mines or in undeveloped mines of demonstrated merit, in Siskiyou county, will learn of several excellent chances for safe and profitable investment by addressing

WANTED FOR CASH,

Second-Hand 3½-Foot

HUNTINGTON MILL

IN GOOD CONNITION.

C., Box A, Mining and Scientific Press.

FOR SALE.

1 Latest Improved Bruckner Furnace.
2 Chlorinating Cylinders of cast iron, lead lined.
1 set Krom Rolls.
The above in use hut a short time. For sale cheap. Address L. C. S., Box A., Mining and Scientific Press Office, S. F.

INVENTORS, Take Notice!

L. PETERSON, MODEL MAKER,

226 MARKET ST., N. E. Corner Front (Up Stairs), SAN FRANCISCO. Experimental machinery and all kinds of models. Tin and brasswork. All communications *strictly confidential.*

Professional Cards.

A. H. RICKETTS, Attorney-at-Law, Mining Patents and matters before the Land Department a Specialty. Crocker Building, Rooms 201, 202 and 203, San Francisco.

WM. GILBERT, B. S., Manager. PRACTICAL ENGINEERING SCHOOL, 205 Goodnough B'ld'g, Portland, Or. Civil, Electrical, Steam, Mining, Assaying. Full charge of plant taught. Circular.

The Evans Assay Office.
W. N. JEHU, - - - - Proprietor. Successor to Jehu & Ogden.
628 Montgomery Street, San Francisco. Rooms 46 and 47 Montgomery Block.
Ore Assays, Analyses of Minerals, Metals and their Alloys, Etc.
LESSONS GIVEN IN ASSAYING.

School of Practical, Civil, Mechanical, Electrical and Mining Engineering.
Surveying, Architecture, Drawing and Assaying.
723 Market St., San Francisco, Cal.
OPEN ALL YEAR.
A. VAN DER NAILLEN, President.
Assaying of Ores, $25; Bullion and Chlorination Assay, $25; Blowpipe Assay, $10. Full Course of Assaying, $50. Established 1864.
☞ Send for Circular.

JOHN W. GRAY, Engineer and Surveyor.
Examination, Surveys, and Reports upon Mines, Drainage, Tunnels, etc.
Development of water for mining and domestic use, irrigation, and the production of power. General Surveying of all kinds, and plans prepared. Construction work superintended. Correspondence solicited.
Res.—923 Linden St., Oakland, Cal.

Almarin B. Paul, M. E.,
Mining Operator,
ROOM 5, CROCKER BUILDING.
Cor. Market and Montgomery Sts., San Francisco.
Will give attention to the sale of and reporting on RELIABLE Mining Properties, or the procuring of suitable Machinery for interest in Developed Mines.
Plans and Estimates made for IMPROVED CYANIDE PROCESS PLANTS, and competent instruction for working the same on a large, practical scale.

Mechanical Progress.

Economy of Power-House Operation.

By J. B. Craven.

"Economy of Power-House Operation" has been so often and so thoroughly discussed that I do not know that I can say much that is new on the subject, and yet being one that must ever come up before the management of a street railway system. Starting from the boiler room, we come at once to the place where, in most cases, the greatest waste will be found. It has been said that the waste due to improper firing is often of greater consequence than any other loss which is produced in the operating of a steam plant. There are two causes for this: First, poor construction of the boiler; second, poor firing and lack of care of the boilers. Most of us think that any man can fire a boiler; and while looking with awe and wonder at the engine and generator, forget that all the power comes from the coal pile, and pay little attention as to the economy in transmitting that power from the coal to the engine. No greater mistake is made than to place the care of boilers in incompetent hands, for they require the highest degree of care, conscientiousness and constant attention.

The fireman must be ever on the watch to see that the water is kept at the proper level to keep an even steam pressure and to show by his steam, coal and water records that he is getting just as good cards as the engineer can show by the manipulation of the steam he uses in his engine. He must see that the fires are spread evenly over the grates and are of an even thickness, that the proper amount of air is admitted into the furnace to obtain good combustion.

If you could realize how easily from one to twenty per cent of coal can be shoveled into the furnace and up the chimney without generating any more power, you would see how essential it is to have something more than mere machines shoveling coal into a furnace. Another point of importance is to see that boilers are kept clean and free from scale, which is simply the result of improper attention.

If for a moment you will stop and think that in the construction of the boiler the maker has reduced the thickness of the tubes as much as possible consistent with safety, and then look at a tube with from one-eighth to one-half an inch of scale on it, you will at once see how great the loss must be transmitting the heat through this scale. Not only that, but it leaves the iron exposed to the effects of the heat without the proper circulation of water back of it, which causes rapid deterioration, and in some cases is liable to cause an explosion. I have used quite a number of boiler compounds for the prevention of scale, but have found the best to be plain coal oil. We have used it in Buffalo for the past two years with success, putting about one pint a day into each boiler and letting it enter with the feed water by means of a sight-feed lubricator. However, no one remedy will fill all cases, and each must be the subject of some experiment.

Another source of loss comes from insufficiently covered boilers and pipes. See that all exposed parts, that possibly can be, are covered with some good non-conducting material, and prevent as much as possible radiation and condensation. The steam pipes should be kept tight and all leaks followed up at once and stopped, and in this way have as little loss as possible between the boilers and engines. See that the piping is well drained, so that water will not carry over the cylinder of the engine. This is accomplished by separators placed as near to the engine as possible, and the water thus separated is returned to the boilers. In a good many cases this water is allowed to go to waste; if this is found to be the case, it should be remedied, as this water is separated at a very high temperature, and requires very little heat to turn it again into steam. Before entering the engine-room I would like to say something on the subject of feed-water heaters. If your engines are running non-condensing, the question is very easily settled. As, however, the majority of steam plants are run condensing, other factors are brought in. In the power-house of the Buffalo Railway Company, one-seventh of the engine capacity is run high pressure. In this way, taking the feed water from the hot well at an initial temperature of 110°, and passing it through two heaters in the exhaust line of the high-pressure system, we get a final temperature of 194° before the water enters the boilers. It is claimed by some that this method of taking the water from the hot well is not right, on account of the oil to be found in this water. But so small a portion of the hot well water is used that the amount of oil in it is small, and by this method we do away with secondary heaters in the exhaust line, between the engine and condenser, and not only save in the first cost, but I think obtain slightly better results. However, one thing is important—whatever means are used to heat the feed water, it should be done, for not only will there be a great saving in fuel, but the straining of the boilers due to putting cold water in will be done away with.

Passing from the boiler room we come to the engines and generators, and the types seen here will be many and varied, from the high-speed, belt-driven machine to the slow-speed, direct-connected machine of large units. As you all know, the tendency of late has inclined to the use of the latter type. In my mind there is no doubt of the efficiency of the direct-connected unit over the belted one. It is evident to all that where space is valuable it has the advantage of taking up less room. They can be thrown in and out of service with as much rapidity as the belt-driven machine; there is a saving of one and one-half to three per cent, due to the slipping of belts, very little in itself, but when figured up at the end of a year in a plant of any size will amount to considerable.

Added to this there is the saving in labor and the decreased expense due to wear and tear, as this item is less in slow-speed than in high-speed machinery. For the above reasons I have drawn the conclusion that direct-connected units are more economical than high-speed ones. Regarding the size of units used, it depends entirely on the output of the plant. I would advocate as large as possible, yet not so large that the breaking down of one would cripple the output. However, in plants that have not these latest types of machines, great saving may be made in the operating of the engines. In many cases, after the constructing engineer has left, engines are oftimes supposed to look after themselves, those in charge simply supplying them with steam and oil. What I said in reference to the man in charge of the boiler room applies with equal force here. Put a thoroughly competent man in charge and you will find it a paying investment. Intelligence and experience are the best safeguards and the real insurance against accidents. Fifty dollars a month more to a capable engineer will probably be repaid a hundred times by the care taken and the high state of efficiency at which the machinery is kept. In such a state an engine is a reliable piece of mechanism. If neglected it is liable to fail at any time, causing delays and worries, and not only adding to the expense in the cost of repairs, but a loss in the receipts outside.

A capable engineer will see that his engines are indicated at least once a month, to see that the valves are properly set, and so keep the steam consumption down to a minimum. All pounding, knocking and leaks should be followed up and remedied at once, and the engines kept in such a state as at all times to be ready to perform the severest service exacted of them. Always keep the load as near the normal capacity of the engines as possible, as engines at that point are most economical; besides, you will have fewer machines in service, and thus save in the oil supply. Here I will say a little on the subject of oil, as I think quite a saving may be made at this point. In fact, I have had one engineer use $640 worth of oil more in six months than another engineer used in the same time, and the engine capacity was increased during the time the last man was in charge. The lowest-priced oil is not always the cheapest; some oils will go much further than others, and the question of what to use should be settled only by careful examination. After being used once it can be filtered and used again on the lighter parts of the machinery. If rags are used for wiping instead of waste they can be washed and used again, and the grease and oil extracted will be found useful in some part of the system. By washing the rags eighty per cent can be saved over what the cost would be if only used once and thrown away. Coming to the generator, we find a machine that is usually well made and efficient. Keep them dry and thoroughly clean, and have the commutator kept as smooth as possible. The principal trouble will be found in the sparking of the brushes and the heating of the armature and the field coils. The causes of these troubles are too many to enter into here, but on the appearance of trouble the machine should be stopped as soon as possible, for the old maxim "A stitch in time saves nine" can be applied here. Keep the minor electrical apparatus in a station. Everything, such as switches, connections and all instruments, should be kept clean and in working order, especially in the case of lightning arresters, as they may be the means of saving an armature.

Three-Cylinder Simple Locomotives.

The use of a third cylinder on a locomotive, where the latter is a compound engine and the steam has two chances to expand, is no novelty. Such a plan is quite common in Europe, but a three-cylinder locomotive of the single expansion type is much more unusual, and, indeed, was unknown until quite recently. It is an American invention, too. About ten years ago it was found that stationary engines in the coal regions, employed to haul cars up a steep grade on short inclined planes, would pull more steadily if three cylinders, working cranks 120 degrees apart, were resorted to than would those with only two. The idea was conceived by the late John B. Smith, president of the Erie and Wyoming Valley Railroad Company, and was put into practice by him. He did not expect to get more power from the same steam, but to apply the power more evenly. The work of a piston depends on the leverage which it gets on the crank, and this varies during the stroke. By the proposed change it was hoped to get a better distribution in the general result. The experiment so fully justified Mr. Smith's expectations that the principle was applied to several small locomotives. These, too, developed the same qualities as the stationary engines; and now, within two or three years, six large engines, mostly for freight service, have been built with three cylinders.

TUBBS CORDAGE CO.
(A CORPORATION.)

Constantly on hand a full assortment of Manila Rope, Sisal Rope, Duplex Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc. Extra sizes and lengths made to order on short notice

PLACER
Amalgamators,
Dredgers,
Shovels.

Complete "Lancaster" Gold Amalgamating, Concentrating and Hoisting plants furnished for treating large quantities of low grade placer ground at a small cost with minimum supply of water or compressed air.

Highest possible Gold yield insured.

Outfits include "Lancaster" 1895 Land or River Dredges, Grapples, Scoops, Steam Shovels and Cableways of the most approved construction. Success guaranteed. Capacity, one hundred tons hourly and upward, if required.

Crushing, Pulverizing, Concentrating and other machinery also built.

Investigation solicited.

HEALD'S
Business College,
24 Post Street, - San Francisco.

FOR SEVENTY-FIVE DOLLARS

This College instructs in Shorthand, Type-Writing Bookkeeping, Telegraphy, Penmanship, Drawing, all the English branches, and everything pertaining to business, for full six months. We have sixteen teachers and give individual instruction to all our pupils.

A Department of Electrical Engineering
Has been established under a thoroughly qualified instructor. The course is thoroughly practical. Send for Circular. C. S. HALEY, Sec.

BACK FILES of the MINING AND SCIENTIFIC PRESS (unbound) can be had for $3 per volume of six months. Per year (two volumes), $5. Inserted in Dewey's patent binder, 50 cents additional per volume.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

GOVER.—*Republican:* The water is still heing kept out hy means of the electric pump. W. T. Hale, of the Keystone, resigned his position as superintendent on the ground that he was not ahle to attend to it. Wales Palmer is now in charge of the property for J. M. McDonald. The sheriff's keepers are still in charge under the attachment suit. Word was sent up to the superintendent last week to start up the mine. This can hardly be done without settling the indehtedness, and from these instructions the inference is that there is some prospect of a settlement.

ANITA.—Tbe miners are again laid off; too much water, which cannot be controlled by present facilities. The superintendent proposes putting in a steam pump.

ALMA.—The new hoisting machinery from the Risdon Iron Works is all on the ground, and, with the exception of a few pieces, is all in place. It is a douhle-cylinder engine, 100-horse power. Everything in connection therewith has heen done in the most suhstantial manner.

THE KEYSTONE.—The Keystone mill was started yesterday morning, after an idleness of only seven weeks as a result of the fire. This is the quickest resuscitation for a quartz mill on record in this county, especially considering that the work had to he done in the dead of winter, when material is difficult to get.

Inyo.

DRY PLACERS.—Placer gold was discovered near Independence in paying quantities twenty years ago, hut at that time the miners, where they could not ohtain water, had to haul or pack their dirt, but with the dry washer those diggings are now heing worked. Gold was discovered last May in Mazourka canyon by some Mexicans, and ahout thirty men have heen engaged iu mining there ever since. This discovery led to others, and now there are a number of places where gold has heen found in paying quantities. The gold is found in the Inyo range of mountains, although not very rich or very extensive, yet in the aggregate a considerahle quantity has been taken out, and from present indications more will he taken out the coming seasou than there was last. The season for dry washing will commence in May and last until the first rains in the fall, prohably Novemher, when it must cease, as the ground gets too wet to he worked hy that process.

E. C. Garlick, superintendent of the Argus group of mines, has concluded all the arrangements for water and mill sites and has gone out to Snow's Canyon with a supply of provisions and tools.

Nevada.

RICH QUARTZ.—Some remarkahly rich quartz is heing taken from the Trevaskis ledge near Indian Flat. Eight pans of rock, weighing in all ahout 160 pounds, was pounded up a few days ago and yielded $219.43, the gold being worth $17.09 per ounce. This is the mine on which Prof. George A. Treadwell bas a hond, and is endeavoring to get English capitalists to buy the property. A *Transcript* reporter was shown a pan containing a prospect obtained from nine pounds of quartz. The bottom of the pan was covered with gold, scattered all through the fine dirt and sand. It was estimated that there was about $40 worth of gold in the pan. Mr. Treadwell intends sending this prospect to England without removing the dirt or small pieces of rock that were left, in order that the parties who are thinking of buying the mine may get a hetter idea of what the rock contains. The quartz was taken out ahout eight feet helow the surface, and the vein matter is ahout eighteen inches thick.

DRIFT MINING.—At the Odin drift mine, a short distance north of Nevada City, tbe tunnel has been driveu through 90 feet of granite, and it is calculated that ahout 100 feet more will have to he run hefore the channel is reached. The indications are encouraging, and it is helieved that a large deposit of rich gravel will he found when the channel is struck. The tunnel at the East Harmony has heen extended 100 feet, and a raise of 40 feet made. Some splendid gravel is heing taken out.

THE RICH MARYLAND. — *Telegraph:* The Maryland Mining Company has heen having considerahle trouhle with water and pumps of late, hut now all is serene and the men all went to work. The new find in the 16-foot level is proving to be exceptioually rich. Men who have heen working there for years say that they never saw anything like it before.

HAGUE'S BIG ENTERPRISE. — *Herald:* On Monday hegan the survey for the proposed pipe line from the Empire mine to Massachusetts hill, in Grass Valley district. Mr. Hague's contemplated operations in that district will involve an outlay of at least $100,000, and it is said that the work will surely he commenced this spring.

RIDGE MINE.—Richard Phelan, the superintendeut of the Gold Ridge Con. Miniug Co., whose property is located on the San Juan ridge, writes to the *Herald* that the company owns 200 acres of ground; that they have a good natural dumping ground which cau be prepared at moderate expeuse to hold their debris for three years, and that they will he ready to hydraulic by next June. The company will also erect a quartz mill, as the property includes four quartz claims. The gold in the gravel claims comes up to the grass roots, and there is no foreign rock or anything else hut hlue gravel, apparently with very little cement. Such a mine ought to prove a fine gold producer.

Shasta.

A GLOWING ANTICIPATION.—From Redding it is asserted that "the new company which recently hought the Iron Mountain mine are straining every energy in the preliminary work, preparatory to huilding a hroad-gauge railroad to the mine and securing a site for the great copper-matting smelter—the largest on the Americau coutinent—which they hope to have in operation hefore the 1st of October. The capacity of their plant will not he less thau 1000 tons daily; mayhe 1500 tons of Iron Mountaiu ore. That will give a local market for 250 to 300 tons of silicious ores that other mines will produce.

"It will put from 12,000 to 15,000 men to work in the hills around Redding, and give her fruit-growers a splendid local market for their orchard products. In three years, or less, Redding will he leading Butte, Moutana. This is no fancy dream, but it is a reality which this great reduction plant guarantees.

"The company's attorney, who came out from New York to attend to the legal matters, says Shasta will he the greatest metal producer of the Pacific coast inside of three years. Just think of a mine showing a hreast of ore 700 feet wide, that will average from ten to thirty per cent copper, thirty ounces in silver and $3 in gold! That is Iron Mountain."

Siskiyou.

MINING NOTES. — Yreka *Journal:* The Greenhorn hlue gravel mine, ahout a mile south of Yreka, seems to he improving in its gold yield, hy the drifters reaching richer gravel, and obtaining a greater ahundance of water for more successful operation in sluicing, siuce the weather has become warmer to melt the snow on the mountains. The cleanup last week amounted to $1326, and will prohahly average that amount steadily from now on, the greatest drawhack heretofore being the scarcity of water for washing.

The river miners in the Honolulu district, of Klamath river, will soon commence getting timhers and lumher ready for wing-damming, hut it will he some time yet hefore anything can he done in this respect at Oak Bar and Hamburg, farther down, in the vicinity of Scott river.

Great preparations are in progress for extensive mining operations at South Fork of Scott river, and around Callahan's. The Enterprise Co. is huilding a ditch two miles in length to their claim on Wild Cat, and the Scott River Mining Co., at South Fork, is also busy getting ready. Other mine owners are doiug likewise. When under full headway, many men will he employed, as the great amount of suow on Scott mountain, to keep up the water supply, will enable the companies to work full handed in sluicing down the great hanks of auriferous gravel in that rich mining district.

MINE BONDED.—*Journal:* Messrs. Hunter and Nolton have honded the mining ground of Quinue & Simmons at Hawkinsville for $20,000, and are to pay Quinne $2000 additional for an equal share in his electric light plant ditch, for extension of same farther down Shasta river, in obtaining greater fall as power in operating a 200-horse power pump. This pump will be used in raising water some 400 feet, for supplying a ditch with 300 inches of water, which will be built from a reservoir at top of the hill above the electric light works down to the diggings at Hawkinsville.

THE BLUE GRAVEL MINE.—The Blue Gravel mine, Greenhorn, has twenty-five men at work. They clean up from $1300 to $1500 a week.

Trinity.

NEW RIVER.—This camp needs transportation facilities. The nearest point of supplies is Callahau's, forty-five miles distant. The Denny & Bar Co., during the summer season, keep a pack train between Callahan's and New River, which last year made 12 trips to New River, carrying 100,000 pounds of freight.

Probahly the best mining property in the quartz line is a new discovery, known as the Surprise, made a year ago by A. O. Fulmore & Co. They have made only one crushing of about forty tons of quartz, which proved immensely rich.

The Mountain Boomer, which a few years ago had heen almost sold to John Daggett for $50,000, has, since its discovery in 1885, as mint receipts will show, yielded an aggregate of $200,000, and is still in good paying condition.

The Sherwood mine, which at present is in the hands of the Prohate Court at Weaverville, has also since 1885 produced not less than $150,000.

The Hard Tack, Tough Nut and Excelsior are three more mines of tbe old discoveries made when the camp was in its infancy in '85, which come next in gold production.

TRINITY CENTER.—At Trinity Center there is twelve feet of suow on the summit of the mountain, necessitating ahout six miles of snowshoeing to travelers. The Center and vicinity expect a boom. Besides the Strode and other properties that are paying well, new developments are heing made. The old Nash mine on Coffee creek, which has changed hands, has heen paying $10 per man to the force employed in drifting and prospecting, and it is the intention to put ahout 200 men at work in the near future. Wm. Volmers is ahout to build a mill on his location eight miles from the Center.

NEVADA.

Panaca District.

Lode: The recent sale of some mining property in Panaca district is directing attention that way. This district, until ahout a year ago, was known as Chief district, and considerahle miuing and prospecting was done there about twenty years ago. When it was an active little place silver was worth something, and the only mining done was for this metal. During the past few years only gold has heen sought after, hut this section was given very little attention, and while it was generally known that a sample could occasionally he found that would return a couple of ounces in gold, it was also supposed that only a sample could be found. But this state of affairs only proves that mining and prospecting may he well and thoroughly understood hy many and practiced only hy a few. The thorough investigation of the district and the Advance property in particular, made hy the recent investors (Messrs. H. W. Lawrence, P. Sheahan and Wm. Lloyd) has caused the attention that is heing given this section, and we understand that preparations are heing made for active work immediately.

Our hest information on the Advauce is that a shaft 105 feet in depth has a well-defined ledge from the surface to the hottom, with a two-foot streak of ore for the entire distance, giving $41 in gold and twelve ounces silver. Those who are hest acquainted with the district helieve it is a continuation on the north of the famous Ferguson district, ahout thirty miles distant.

The formatiou is principally quartzite. It is located eleven miles south of Bullionville, where W. S. Godbe's great reduction plant is situated. Everything appears favorahle and undouhtedly, with the early opening of spring, a lively camp will come into prominence in the district. We learn that many prospectors from Pioche and Panaca are already in the field, and many of the hoys "have greater bonanzas than can he found in Ferguson district."

ALASKA.

WINTER GRAVEL SLUICING.—*News:* Since the sluice mining commenced on Gold and Lemon creeks, for the past two months between $3000 and $4000 in gold dust has heen shipped through the Juneau bank and hy private parties. This winter more attention has heen paid to ground sluicing, as the mild weather has permitted the work, whereas during other wiuters the weather was too severe for its continuance. The gang of men at Lemon creek is doing mueh hetter than was expected hy the old-timers, who have previously examined the creek hottom.

IN SUM DUM BAY.—On her way up the Topeka called into Sum Dum hay and unloaded a stamp mill at the Bald Eagle mine, and also dropped off N. S. Trowbridge and P. Maul, the superintendent and foreman of the mine, and a gang of workmen. The plant will be sledded on the snow to a point ahout two miles back from the heach and near the mine, and its erection will go forward as fast as possihle. This spring another quartz mill will he crushing out the gold from Alaska ores.

ARIZONA.

The Montaua mill at Oro Blanco has begun operations again.

John J. Dodds and F. J. Lyon, of the Eugene Mining Company of Phœnix, are working their gold properties at Canon. This mining company is composed entirely of Prescott and Phœnix men.

THE RYLAND PROPERTY. — *Journal-Miner:* The Ryland mine and mill on Minnehaha Flat is daily in operation, and the fact of its being so is the hest argument that Mr. Ritchie is making a success of it. Heretofore under every management it has proven a failure. The reason for this can he easily proven. Theory may be all right on top of the ground; but when you go down into an Arizona mine, the only assistance you need is a little practical judgment.

THE VULTURE MINE.—The Phœnix *Review* learns that the Vulture mine will shortly he worked. New machinery will be put in, the pipe line repaired and the mine worked for all it is worth. This is gratifying news, for this mine, though long lying idle, is one of the best gold properties in Arizona. It has heen hadly managed; but under the new management this will he changed. Mr. Sydney Kempton will have charge of the mill.

This famous mine, according to the company's books, has produced $9,000,000 already. It will take some money, perhaps $150,000, to put the property in good running order, after which the mine will be just as hig a produeer as ever. Aside from the amount of gold taken from the Vulture mine as indicated hy the hooks of the company, an equal amount has been stolen by the men working the elaim. All the old-timers of Phœnix remember the good times when the Vulture was running. It will run again, and that in the near future.

BRITISH COLUMBIA.

PRODUCT OF A RUN IN THE CARIBOO MINE.—*Chronicle:* Three gold hricks, containing a small percentage of silver, and weighing 720 Troy ounces, or 60 pounds, and valued at nearly $10,000, were on exhihition at the Traders' bank yesterday. They were from the Carihoo mine, owned hy James Monaghan and other Spokanites, in the Rock Creek district, British Columhia.

The bricks are only worth $13.50 per ounce, owing to the presence of silver. They are the result of twenty-one days' run of the Carihoo Company's ten-stamp mill.

"The mine is going to make the owners all rich," said M. M. Cowley. "The company declared its first dividend to-day and it amouuted to $8000, after dedueting the cost of the mill and other improvements. Who brought the bricks down? Well, we don't care to say much about that. Nobody on the outside ever knows when the bricks are coming, what way they come, or who hrings them. Otherwise they might he intereepted on the way."

GENERAL NOTES.—The Antoine, Slocan, is a new shippiug mine, sending five cars forward this year. Three of those netted $8000.

Big strikes are reported on the Wonderful and Ivanhoe, Slocan. The rawhide trails are heing prepared for hauling.

On the Little Phil, Ainsworth, the ore does not occur in a solid vein, but in the shape of solid galena; a most unusual formation.

The Nelson Hydraulic Mining Company is getting ready to resume work at the earliest possihle date. Two monitors will he worked.

A number of husiness men of Nelson are offering $100,000 in land and money for the erection and operation of a smelter in that town.

The Center Star, which adjoins the Le Roi, Trail Creek, will he ready to ship ore shortly. Upwards of 500 feet of tunnel have heen pierced.

At sixty-seven feet in the Goodenough, Slocan, the vein, which carries ahout six inches of high-grade carhonates, was struck 120 feet from the surface. From this mine twenty-two tons netted $5435.12.

The Kootenay *Mail* gives ore shipments from Slocan hy way of Revelstoke, from Feb. 9th to 15th, as follows: Slocan Star, 370,000 lbs.; Nohle Five, 260,000 lhs.; Idaho, 120,000 lhs.; Reco, 70,000 lhs.; total, 1,820,000 lhs.

The Humphries-Moore concentrator at Three Forks has started running, chiefly on Alamo and Idaho ores, and all available teams are engaged hauling. Probahly Mountain Chief ore will he run through in the spring.

COLORADO.

A CREEDE CONSOLIDATION.—At Creode a consolidation has heen formed of the famous Ridge group of mines, Solomon, Ethel and Holy Moses. Large reduction works will be erected, and all the ore from these mines treated in one mill.

SALES OF MINING PROPERTY.—*Republican:* Four mining deals in Colorado properties were recently closed, so far as honding the properties, and are in a fair way to he quickly cousummated. Two of the sales were well known mines of Gilpiu county, one for a mine and mill in the Holy Cross distriet of Eagle county, and the other is a working proposition for the handling of a large group on the Spanish Peaks.

The Topeka mine, near Central City, was placed for the Argyll Mining Company with H. C. Woodworth & Son, investment bankers, for a price exceeding $300,000. It is one of the great gold produeers of the "Little Kingdom," and is known to hold in reserve great hodies of ore.

The New Centennial is being bought hy a Denver mining man who is always on the lookout for investments. The price is not known.

The Polar Star mine of Eagle county is being sold by F. D. Kiefer, of Grand Junction, to Denver parties for $175,000. With the property, which has produced largely in the past, is a 25-stamp mill, and the sale means a resumption of work to the full capacity of the mine.

IDAHO.

THE STANDARD MINE.—The Union mill has heen put in condition for service the past week for the treatment of ore from the Standard mine, which now employs fifty men. A new ore hin and other improvements have just been completed at the mouth of the main tuunel. The ore is of better grade than the average Cœur d'Alene ore. It is directly tributary to the town of Burke, hut Wallace receives the industrial henefit of the Union concentrator, which is situated at the mouth of Canyon creek. Messrs. Finch and Campbell are the principal owners of tho property. The Banner tuunel, which is the principal avenue into the mine, is over 2000 feet in length.

BOUND TO GET THE GOLD.—The Kootenai Hydraulic Company is hound to get some gold this year, after its many disappointing experiences along the Pend d'Oreille. Reports received from Seven Mile, via Waneta, state that the company has sixty men at work on the foundations for the hig pumps which are to take the place of the enormous diteh and flume originally designed to carry water on to the hars. By the time high water comes, the work will be well advaneed, and it is understood that the entire work is to he finished as soon as possihle. Heavy machinery has been ordered from the East, and before midsummer the managers hope to begin harvesting the gold which they know is seattered all through the big gravel banks.

Along the Salmon river times will be pretty hrisk next summer too. It will probahly he six weeks or more before the season fairly begids, hut already men who own claims are perfeeting their plans for the season's work. A new elemont will add activity to that district this summer—a class of men who don't happen to have cash enough to buy placer mines, but are willing to lahor, and have arranged with the owners to work the claims on shares—a plan which is of henefit to hoth parties, as few of the owners are exactly prepared to hire any large gangs of men to work their claims.

MONTANA.

THE RARUS DEAL. — *Inter-Mountain:* A United States patent to the Rarus mine, granted in 1894 to S. E. Hirbour et al., was filed for record lately with the county recorder. It is rumored that negotiations are ahout completed for the sale of this property for a sum variously estimated at from $300,000 to $400,000. The purchaser whose name is mentioned in connection with the deal is F. A. Heinze. The latter at one time had a lease on the property, and worked it for ahout a year. He had the mine bonded then for $350,000, and it was said made an offer of $250,000 for it, which was refused. It is known that Mr. Heinze has heen anxious to secure another good property in order to keep his smelter running to its full capacity, and mining men are of the opinion that the purchase of the Rarus would be a good investment.

TO WORK RICH PLACERS.—A new plan to handle flat placer ground has heen adopted hy the Gold Dredging Company, to handle the hed sand of Grasshopper creek in Beaver Head county. The company has paid in $75,000 to put on the plant, and start the work. Three and a half miles of creek bed and a large acreage of hars have heen secured. The ground is some of the hest known washings of Montana and has produeed mueh money in the past. The great difficulty in working it has always heen to find dumping ground, the fall of the creek not being sufficient to carry off

the tailings from the sluice. To remedy this the present managers purpose using a dredge to raise the sand, gravel and water into an elevated sluice that gives as much fall as may be wanted.

There is a sixty-five-mile ditch connected with the placers, which gives a 500-foot head at the end and furnishes a supply of 900 inches, with 250 pounds pressure for the operation of an injector to empty the working pit. After carrying off the water of the creek with a ditch along the side, the company first digs by hand a large pit, which is then washed by hedrock sluicing and shoveling the richer sand near it. While this is being done a portion of the pit dammed off is flooded with water and the floating dredge placed on it. Heavy cables stretched from bank to bank at an elevation support on pulleys a swinging sluice box, which is made to move either way as the dredge follows up the bar or moves across the creek. The sluice empties in the pit, which has been cleaned, and as the dredge progresses up the creek the working pit is emptied, the cleaned bedrock refilled and the intermediate pit is being shoveled and sluiced off by a force of workmen.

OREGON.

THE ASHLAND MINE.—*Tidings:* Upon application of the creditors, Judge Hanna at Jacksonville, this afternoon appointed Jos. Dame receiver of the Ashland mine, with bonds placed at $20,000. It is expected that work will go right ahead at the mine as soon as the papers are completed. The total claims represented in liens filed upon the property amount to nearly $8000, $4800 of which are wages due the miners and the remainder material claims held in Ashland.

RUPTURE!

IT has been considered by the medical profession that hernia—commonly called rupture—was incurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But DR. J. C. ANTHONY, of 86 and 87 CHRONICLE BUILDING, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patient no pain, and those living near enough do not lose any time only while in his office once or twice weekly. He guarantees every case he treats, and does not ask a man for a dollar unless he cures him, so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medical College, of New York City.

THE JONES ROCK DRILL

IS THE

Only Successful Hand Power Drilling Machine Ever Invented.

It is strong, durable, reliable, simple, compact, light, easily handled and operated by one man, and will reduce the cost of rock drilling at least Fifty per cent.

Our handsomely illustrated pocket catalogue fully explains the features and workings of the drill. It should be in the hands of every mine owner, lessee, contractor and prospector in the West. *Sent free on application.*

If you are interested in Rock Drilling Correspond with us.

WE CAN SAVE YOU MONEY.

FRANK T. SUTHERLAND, M'g'r Pacific Coast Agency.

Office and Warerooms: 9 FREMONT St., San Francisco, Cal.

Or, Address the Company at its Denver Office.

OUR PIPE

IS FOR SALE.

For Hydraulic Mining and Irrigation Purposes Our Sheet Iron and Sheet Steel Riveted Water Pipe Is Unexcelled.

We Have Also a Large Line of the MATHESON JOINT (Lap-Welded) Pipe, for Which We Are Agents.

Our Prices Are Low; Our Pipe Is Superior, and We Want More Business. May We Quote You Prices?

PIPE FITTINGS, TOO.

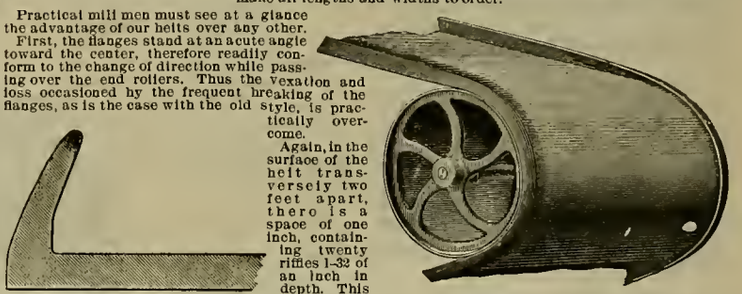
RISDON IRON WORKS,

SAN FRANCISCO, CAL.

Blasdel Improved Concentrating Belt

We keep in stock belts suitable for the Frue, Triumph, Johnston and Tulloch machines, and make all lengths and widths to order.

Practical mill men must see at a glance the advantage of our belts over any other. First, the flanges stand at an acute angle toward the center, therefore readily conform to the change of direction while passing over the end rollers. Thus the vexation and loss occasioned by the frequent breaking of the flanges, as is the case with the old style, is practically overcome. Again, in the surface of the belt transversely two feet apart, there is a space of one inch, containing twenty riffles 1-32 of an inch in depth. This tends to equalize the pulp and prevents it from banking on the edges, or forming channels. This riffle saves fine sulphurets and quicksilver that would escape with the tailings from a belt with an entirely smooth surface.



H. G. BLASDEL, JR., Manager,

419 California Street, Haywards Building.....San Francisco.

Attention Miners!

W. W. MONTAGUE & CO.

—ARE MANUFACTURERS OF—

Riveted Iron and Steel

Water Pipe

For Hydraulic Mining, Mills and Power Plants.

IRON, CUT, PUNCHED AND FORMED, AND TOOLS SUPPLIED FOR MAKING PIPE ON THE GROUND WHERE REQUIRED.

309 to 317 Market Street, San Francisco.

Mining Pipe!

STEEL OR IRON.—We make pipe of either, but recommend STEEL, it being superior to iron in many particulars and inferior in none.

COATING.—We use great care in COATING our pipe with a HOT solution of Double Refined Asphaltum and Maltha.

COMPETITORS.—Our competitors say we have the best appointed Pipe Shop on the Coast.

SCHAW, INGRAM, BATCHER & CO., Hardware Merchants,

SACRAMENTO, CAL.

FRANCIS SMITH & CO.,

—MANUFACTURERS OF—

SHEET IRON & STEEL PIPE

FOR TOWN WATER WORKS.

Hydraulic, Irrigation and Power Plants, Well Pipe, Etc., all sizes.

130 BEALE STREET, SAN FRANCISCO, CAL.

Iron cut, punched and formed, for making pipe on ground where required. All kinds of Tools supplied for making Pipe. Estimates given when required. Are prepared for coating all sizes of Pipes with a composition of Coal Tar and Asphaltum.

CHIME WHISTLES

A thing of beauty is a joy forever.

"LUNKENHEIMER'S" Single Bell Chime Whistles are warranted to please. Constructed on practical principles, producing harmonious sounds. Made in sizes from 2-in. to 10-in. in diameter, with or without valve. Also style for Locomotives.

New Catalogue of superior steam specialties gratis upon request. Consult dealer.

Every description of work plated. Send for Circular.

Electrical Progress.

A PROJECT is under way to dam the Chatahoochee river near Atlanta, Ga., and to electrically transmit some 30,000 horse power therefrom to that city.

ORIGINAL contributions to this department of the paper, of general interest, will be welcomed. No anonymous communication will receive attention.

IN Norway, electrical treatment is being adopted in bleaching pulp. The pulp being placed in the chloride solution, the electric current is turned on, and the operation is completed in from twenty to forty minutes. — London Electricity.

ENGLISH patent number 856, dated January 14th, has been granted to Frederick J. Beaumont and Frederick Hallows of London for an improved registering meter for direct or alternating polyphase, triphase or quadruplephase currents.

AT Reno, Nevada, the Truckee river is wasting thousands of horse power of reliable water power which could be used to advantage at Virginia City, twenty miles distant. There is also a good opening for an electric road for both freight and passenger traffic between the two cities. Most of the freight is now transported by wagons.

HERMAN AERBERTS, of Scheuectady, N. Y., has produced an improvement in electrical measuring instruments, the principle upon which his instruments are based being to send the current to be measured in two electrically parallel branches of circuits round the needle or armature of the instrument, thus exciting in the latter two distinct polarites.

MR. L. W. STORROR, superintendent of the Pacific Postal Telegraph Company, in this city, is one of the ablest men in the business. He is business all through, and although burdened with greater responsibility than any other telegraph man on the coast, his attention is readily secured for the most trivial detail of the business. With such men at the lead any business is bound to succeed.

A NEW MODE OF LIGHTING has been introduced by Mr. Lester Betts, the manager of the Calcutta branch of the Oriental Telephone and Electrical Company, Limited, in the case of the Empress of India Cotton Mills at Budge-Budge, India, which are entirely lighted from the outside, special zinc fittings with fifty candle power lamps being fitted to each window. This system, which has proved a complete success, saves the extra premium for fire insurance.—Electrical Review.

THE Electrical Engineering Company of this city has the contract for the electrical plant for the three new pneumatic guns at the Presidio. There was heavy competition on this contract. The plant consists of a 35 K. W. generator, underground conduit to each gun, and a switchboard. The equipment for each gun consists of three electric motors, each of 18 H. P., and is used for loading and moving the huge gun. This firm has just shipped three direct electric elevator plants to Los Angeles for use in the Whittier Block. They report business steadily increasing in their line.

UNDER the heading of "A Worthy Task for Electrical Inventors," the *Electrical Review* publishes the following taken from the New York *Sun:* "Building water-tight compartment ships like the 'Elbe,' or much better than the 'Elbe,' won't prevent some of them from being sunk by collisions. If the 'Lucania,' for example—the last and finest from the shipbuilder's hands—should hit her sister, the 'Campania,' square amidships, the latter would be lost as surely as she would be hurt. The only safeguard for ships at sea is in the faithful use of some more penetrating sound than that of the fog horn, or the invention of some delicate electrical contrivance which shall always tell of another ship's presence in the neighborhood. Where are the wits of our ingenious brothers, the electricians?" Cannot some of our Pacific coast electricians solve this problem?

ACCORDING to *Nature*, trials have been made in London of a new apparatus for extracting teeth by electricity. It consists of an induction coil of extremely fine wire, having an interrupter capable of vibration at the rate of 450 times a second. The patient sits in the traditional armchair and takes the negative electrode in his left hand and the positive in his right. At this moment the operator turns on a current, of which the intensity is gradually increased till it has attained the utmost limit that the patient can support. The extractor is then put in circuit and fastened on the tooth, which, under the action of the vibration, is loosened at once. The operation is performed very quickly, and the patient feels no other sensation than the pricking produced in the hands and forearms by the current. [This was similarly reported ten years ago, but the difference between theory and practice was such as to exclude the operation from general use.]

A Huge Alternator.

A big alternator is now being built by the General Electric Company. It is to be installed for the Edison Electric Illuminating Company at St. Louis, Mo., and will supply current for incandescent and arc lighting and power, and is being constructed on the monocyclic system, employing low frequency of alternations, the armatures of the generators having special windings adapting them for use on circuits with self-starting current motors. The alternator is of 800 kilowatts capacity, has 80 poles, and will be driven at 90 revolutions per minute. The frame casting weighs 35 tons and measures 24 feet over all. The armature is iron-clad and is 16 feet in diameter, weighing nearly 45 tons. The armature will be supported on a 22-inch shaft. The generator will be able to supply, at full load, 667 amperes at 1200 volts, or the equivalent of 16,000 sixteen c. p. lamps.

Electric Power Transmission for Mines.

Probably no other application of transmission of electric power is more appreciated than in mining. In some instances the geological location of the mine renders a supply of fuel either entirely out of the question or very expensive; but the principal reason in favor of such application appears to be that in almost every instance ample water power—cheapest of all known sources of power—is within available distance from the mines, where, with a single source of power from one generator operated by a water wheel, transmission is readily and economically made not only to one, but to any desired number of locations in and about the mines, as is best suited to the requirements of the work to be performed.

A splendid illustration of such application is in operation at the Mammoth mine, situated in Nevada county, California. This plant is reported to have been run continuously day and night for the past year, stopping only for "cleanups," and without the expenditure of a cent for repairs or renewals, or the loss of a moment of time. Such a record would, of course, be an impossibility ordinarily; and in some cases, as, for instance, in the operation of mine pumps, it presents important features for consideration.

At the Mammoth mine the power station is located at the base of a ravine on the headwaters of the Fresno river, where a short ditch only was necessary to obtain a fall of sixty-three feet. From the end of the ditch the water is conducted to the wheel through a twenty-eight-inch pipe, 230 feet long. The power station consists of a three-nozzle, sixty-seven-inch Pelton water wheel running under a head of sixty-three feet at 109 revolutions per minute, and having a maximum capacity of 175-horse power.

The power is transmitted from the wheel to a countershaft by seventeen one and one-half-inch manilla ropes, giving the countershaft a speed of 300 revolutions, from which is driven by belt connection an Electrical Engineering Co.'s type C generator of 125-horse power. The current is carried to the mine, 8000 feet distant, by bare copper wires at a pressure of 1000 volts and supplies four separate and independent motors which operate a twenty-stamp mill and rock breaker, concentrator pump on central lift and a set of hoisting works. As the hoisting works require about fifty per cent of the power generated and are continually starting and stopping, throwing the current on and off instantly, regulation at such high pressure and under such great variations of load proved one of the most trying propositions encountered. This, however, has been successfully accomplished by use of the Pelton differential governor on the water wheel, which, it is said, maintains a uniform voltage under any and all of the variations incident to the operation of such a variety of machinery in an intermittent and irregular way. On account of the peculiar local conditions, this plant has attracted no small amount of attention from capitalists and from scientists, and its complete success has demonstrated that a comparatively large amount of power can be procured by this means, and run at a merely nominal cost as compared to steam, and without the inevitable delays incident to steam-power systems.

It is predicted that the day is not far distant when every large mine in the country will have adopted electric power, and that such adoption, in view of superior advantages for continuous service, as shown in the record of the Mammoth mine outfit, will result in the more general use of convenient water power.

SEAMLESS TUBE HOSE.

Our patented Seamless Tube Hose is the most valuable improvement made in hose in recent years. In the old way the tube is formed from a sheet of rubber, fifty feet long, of a width to encircle the hose pole, lapped and cemented (many times imperfectly), and the water gets through to the canvas and rots it, and the hose bursts. Our seamless tube is run the same as lead pipe is made and is free from defects. This process is employed in all sizes from one-half inch to the largest fire hose. Buy these goods and you are sure to get the worth of your money.

Tremendous Pressure.

A wonderful machine, which is not only a prodigious and terrible piece of enginery, but an allegory, is called a testing machine, and is used to ascertain the resisting power of various materials. It is not content with finding out that a beam of oak, for instance, will bear without breaking a pressure on one spot of 160,000 pounds; the beam must be utterly crushed each time the test is made, and note must be taken of the exact weight that lay upon it at the moment of its final dissolution. Day after day this great machine heaves and strains itself and bears down with slow and awful force upon some tough beam or block of wood; and whether the timber is placed flatwise and needs, say, but a paltry seventy-five tons to crush it, or whether it be placed endwise like a pillar, and will hold up twice as much weight before it cries out and gives up the ghost, it must yield just the same and surrender its pitiful crushed frame to be photographed and studied and picked to pieces for the benefit of science. That is the machinery; the allegory lies in the thing by the force of which this monstrous pressure is exerted. It is oil, nothing but suave, gentle yielding oil, the emblem of softness and agreeableness.

There is a certain piston in this mechanism which, pressing against a quantity of oil in a confined space, forces this oil against another iron surface, which in turn presses forward upon the timber, so that all this crushing power is exerted by the medium of nothing but oil. It is the oil that does it. The foreman stands over his great machine, his pupils grouped about. It lies down flat on its great back, like a giant bracing his shoulders against a rock to push with his feet. The thing which he is pushing against is a beam of seasoned oak, about ten inches square, and the thing with which he is pushing is another and lengthwise square beam of oak, the end of which is directly against the side of the beam to be crushed. Off at one side, apparently unconnected with the machine, but in reality connecting with it, is an apparatus where there are levers, comparable to the throttle valve of a locomotive, and a gauge which registers accurately the pressure that is being exerted. A young learner stands at these levers and this gauge, and when the foreman says, "Turn on more oil," he moves a lever and the pressure rises. Seventy thousand pounds, 80,000 pounds, it rises rapidly. The lengthwise beam is sinking itself deep into the side of the victim timber, but this still holds out bravely. The pressure rises to 90,000—100,000 pounds. The watchers all gather around the center of the pressure in anticipation of the catastrophe; the lengthwise timber is squeezing into the solid oak of the other one as one's thumb might be driven into a piece of cheese.

But still it holds. Little by little the power is turned on. The young man at the gauge calls "120,000," "130,000," "140,000," "150,000;" you hear the snapping of a myriad of tendons within the beam, and all these sounds join in a sort of low buzzing roar or cry, which suggest an elemental agony. One hundred and sixty thousand pounds—the beam sinks deeper into the flesh of its victim—170,000—"More oil!" and now the crackle rises—the lengthwise beam itself begins to crack, and the other beam, yielding at last, goes to pieces all at once: and when the pressure is removed it is taken out, twisted, contorted, riven, pierced, crushed.

It is useful service, after all, though it seems but an exhibition of the brutality of mere mechanism, that the testing machine and its bed of oil have done; for since it began the work it has proved that timbers will staud about one half the weight which the accepted authorities said they would stand; and by introducing a more conservative weighting of wood has doubtless saved many human lives from destruction by the collapse of timbered structures.

Hot Salt Solution for Relief of Short Hemorrhage.

Dr. Wyeth, speaking at the meeting of the New York State Association of Railway Surgeons, strongly recommended the injection into the circulation, through a vein, of hot salt solution to take the place, in part, of the volume of blood which has been lost as a result of accident. "The solution which I have employed, running in as much as five points in a single operation, is composed of clean water, which has been boiled and allowed to cool to 110° or 120° F., or just as hot as the hand can bear, to every pint of which a teaspoonful of common salt is added. I have seen the pulse go from 140, in cases of tremendous hemorrhage, steadily down to 70 to the minute within two minutes of the injection of a pint of this solution. While it may be used cooler than 110° F., and in some emergencies this may be necessary, it is safer to give it as hot as 110° to 120°, because the cold solution robs the body of its heat, while the hot solution carries heat with it, and thus adds to the maintenance of the normal temperature. The apparatus is simple, a metal or glass pipette to go into the vein, a rubber tube three or four feet long and an irrigator bag or vessel."

THE Boxer, the latest torpedo boat built for the British Admiralty, is 201½ feet long, 19 feet beam; draught, loaded, 7 feet 2 inches. On a recent trial trip the mean speed on six runs over the measured mile was 29.314 knots, or 33¾ statute miles, per hour.

DEWEY & CO., 220 Market St., SAN FRANCISCO,
PATENT SOLICITORS.
ESTABLISHED 1863
Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S.F.

Market Reports.

The Markets.

SAN FRANCISCO, Feb. 28, 1895.

Silver appreciated a trifle during the week. It is believed that it will not again go below the 60 mark. The story is again told, with considerable semblance of truth, that the reason British capitalists are now inspecting and securing promising silver properties in the northwest is the prevalent British belief that favorable British legislation toward the white metal is one of the assured events of the near future, and that inside of a year the British parliament will tacitly recognize every claim put forward by the friends of silver or the political economists who recognize the necessity of a bimetallic policy.

In 1864 the price of bar copper in New York City was 55 cents per pound. Despite the enormous consumption of copper occasioned by the great advance in electrical equipment, copper is quoted to-day at 9¾ cents, with a downward tendency. In the same year galena sold for $225 per ton and lead for 25 cents per pound: to-day it is slow of sale, in New York, at 3¼.

Mining Share Market.

SAN FRANCISCO, Feb. 28, 1895.

Last week the little bears had things their own way. This week there was an upward tendency, prices holding strong through the week, particularly on the north end stocks.

The Con. Cal. & Va.'s bullion output for February was $51,081.84, on which there was a $10,000 profit for the company. Supt. Lyman gives very good reports of the mine during the week. General reports from the Comstock are favorable.

The following mining companies have been dropped from the list of the San Francisco Stock Exchange for non-payment of the annual dues: Baltimore, Grand Prize, Navajo, Belle Isle, Commonwealth and Mayflower.

The auction sale of the delinquent stock of the Yellow Jacket mine was held by Sheriff Quirk at the office of the company in Gold Hill Wednesday afternoon, says the Virginia *Enterprise*. Out of the capital stock of the company only 376 shares were delinquent, the assessment of twenty-five cents per share having been collected on the balance. The highest bidder was H. S. Beck, who bought the forfeited stock at 37½ cents per share.

The new commission rates adopted by the Denver Exchange go into effect this week. On stocks selling at 2 cents and under the broker is allowed ⅛ cent a share; from 2 to 10, ¼ cent; from 10 to 25, ⅓ cent; from 25 to 50, 1 cent; from 50 to 75, 1½ cents; from 75 to $1, 2 cents; from $1 to $2, 2½ cents, and above $2, 1 per cent on the money handled—a little difference from the Pine street tariff.

The following illustrates the changes of the week:

SUCCESSIVE strikes of miners in Eugland and Scotland are said to be rapidly developing the coal production of India.

THE Kougo railroad has cost $62,000 per mile, which is just double the estimate.

ABOUT five-eighths of the steamers in the world are under the British flag.

A SHORT TIME AGO the mill of Smith Bros. & Co., at Portland, Or., made the largest cut ever made at the mill, running on spruce stuff. Simonds' "B" pattern saws were used. The foreman, Mr. Flood, believes the Simonds saws have no equal.—West Coast Lumberman.

534,516.—MAGAZINE GUN—B. F. Pettit, San Luis Obispo, Cal.
534,374.—DENTAL TOOL—O. H. & A. F. Piper, San Jose, Cal.
534,519.—ELECTRIC RAILWAY—A. Rosenholz, S. F.
534,527.—RIVETING MACHINE—J. I. Smith, Chico, Cal.
534,452.—KEY RING—J. C. Schlarbaum, S. F.
534,285.—VEHICLE SEAT—T. C. Shankland, Oakland, Cal.
534,591.—LUBRICATOR—Wible & Pressey, Arcata, Cal.
534,309.—COLLAR BUTTON—G. H. Williams, Los Angeles, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

CONDUIT ELECTRIC RAILWAY.—Alfred Rosenholz, San Francisco, Cal., assignor of one-half to Samuel J. Clarke and Harvey S. Brown. No. 533,610. Dated Feb. 5, 1895. This invention relates to improvements in conduit electric railways. It consists of a slotted tube or tunnel; a main conductor or conductors extending parallel therewith and having branch wires leading from the main conductors into the tube or tunnel; tilting arms with which these wires connect, the arms acting as switches to turn on or cut off the current. A conducting wire is stretched between automatically adjustable arms which project through the slot into the tube or tunnel from opposite ends of each car. This wire forms contact with rollers over which it passes at each of these switches, and when this contact is formed, a current of electricity will pass through the wire to the motor mechanism on the car. As soon as the car has passed the switch, the latter instantly cuts off the current, while the car forms contact with the next successive switch, and so on from one end to the other, a new supply of electricity passing in at each successive contact. The main conductors passing through a sealed and insulated-containing tube, all leakage and loss of electricity is thus prevented.

HOISTING AND CONVEYING APPARATUS.—Louis Rosenfeld, New York, N. Y. No. 533,669. Dated Feb. 5, 1895. The object of this apparatus is to effect the forward and back travel of the load while being suspended at any height without the use of latches, and to enable the load to be raised or lowered at any point. The apparatus consists of a sheave carrier, by which is meant a frame containing a pair of sheaves; means whereby the sheave carrier is caused to travel forward and backward, a load rope, the ends of which are guided to the load by the sheaves of the carrier, and whose hight passes freely through a running block, and a hoisting line connected with the runuing block.

FOR SALE.

The Whole or Half Interest in a good quartz mine (last assay $70.34 per ton). Three immense ledges of 4000 feet long, 600 feet wide, crosscut showing thirty feet of quartz; plenty water and timber on the ground; only three miles from melting works; good reason for selling. Selling price, $30,000 for whole mine. Address
E. R., 1405 Bush St., San Francisco, Cal.

Assessment Notices.

FAIRFAX VILLA COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Fairfax, Marin county, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 19th day of February, 1895, an assessment, No. 2, of one hundred dollars ($100) per share was levied upon the Capital Stock of the Corporation, payable immediately in United States Gold Coin to the Secretary, at the office of the Company, Room 56, No. 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 26th day of March, 1895, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the 16th day of April, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

J. STADTFELD, Jr., Secretary.

Office—Room No. 56, No 309 Montgomery street, San Francisco, California.

CHALLENGE CONSOLIDATED MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Gold Hill, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the nineteenth (19th) day of February, 1895, an assessment (No. 18) of Five Cents (5c) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the company, Room 35, third floor, Mills Building, corner Bush and Montgomery streets, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the twenty-sixth (26th) day of March, 1895, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on TUESDAY, the sixteenth (16th) day of April, 1895, to pay the delinquent assessment, together with cost of advertising and expenses of sale.

By order of the Board of Directors.

C. L. McCOY, Secretary.

Office—Room 35, third floor, Mills Building, corner Bush and Montgomery streets, San Francisco, California.

BOOTH GOLD MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Auburn, Placer county, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the eighteenth day of February, 1895, an assessment (No. 5) of Two (2c) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, No. 310 Pine street, Room No. 28, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the twenty-fifth day of March, 1895, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on WEDNESDAY, the seventeenth day of April, 1895, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

GEO. R. SPINNEY, Secretary.

Office—No. 310 Pine street, Room No. 28, San Francisco, California.

THE CALIFORNIA DEBRIS COMMISSION, having received applications to mine by the hydraulic process from A. Blair, in the American House Mine, near La Porte, Plumas Co., Cal., to impound tailings behind dams in the American House Ravine; from Jay E. Russell, in the Spring Tunnel and Spring Canyon Mines, near Mount Gregory, El Dorado Co., Cal., to impound tailings behind brush dams in Spring Canyon; from Porter Phillips, in the Mount Gregory Gold Mine, near Georgetown, El Dorado Co., Cal., to impound tailings behind brush and log dams in a ravine below the mine; from Wulff Bros., in the Deer Valley Mine, near Green Valley, El Dorado Co., Cal., to impound tailings in an old hydraulic pit; from John Enos, in the Strawberry Placer Mine, near Vallicita, Calaveras Co., Cal., to impound tailings behind rock dam in a gulch below the mine; from Geo. R. Evans et al., in the Red Hill and Telegraph Hill Mines, near Ranchería, Amador Co., Cal., to impound tailings behind log dam in Chili Gulch; and from Moy Jin Mun, in the Grizzly Hill Mine, near Volcano, Amador Co., Cal., to impound tailings behind brush dam in a ravine below the mine, gives notice that a meeting will be held at Room No. 22, Flood Building, San Francisco, Cal., on March 18th, 1895, at 1:30 P. M.

SACRAMENTO, CAL.

BACK FILES of the MINING AND SCIENTIFIC PRESS (unbound) can be had for $3 per volume of six months. Per year (two volumes), $5. Inserted in Dewey's patent binder, 50 cents additional per volume.

Coast Industrial Notes.

—The advent of pennies is reported in Seattle, Wash.

—The Great Northern in Washington State has contracted for 350,000 ties to be delivered by June 1st.

—The revenue steamer Rush is to have an electric light plant. Bids close at the Custom House next Monday.

—During 1894 the Arizona Company at Flagstaff, Arizona, shipped 148 carloads of pine lumber to Los Angeles.

—Lumber exports from the Puget sound district in the month of January amounted to 4,971,000 feet, valued at $41,105.

—Centralia, Wash., has voted in favor of issuing bonds to purchase an electric light plant for $13,000, the bonds to run twenty years.

—The Coast and Geodetic Survey steamer Hassler, now at Tacoma, is ordered sold. She was built twenty-five years ago, and cost $70,000.

—The Sunset Telephone Co., has about completed arrangements to connect this city, Stockton, Sonora, Angels, San Andreas and intermediate places.

A carload of eggs laid on the Pacific Coast was sold to a Chicago dealer this week. This is the first time California eggs were ever sold east of the Missouri river.

There are said to be nearly 100 steam vessels in Alaskan waters that are never inspected, says Supervising Inspector Birmingham. It is practically impossible to do so, by reason of inaccessibility.

—The owners of the steamer Alice Blanchard, are negotiating for the purchase of a large steamer which is to be put on the route between Alaska and San Francisco, calling in at Portland, Coos Bay and Eureka.

—The Market Street Railway Co. are pushing their electric railway schemes, and propose displacing the cable system on Market street by electric cars. They are also building two electric roads from First avenue to the ocean.

—It is seriously announced that the Great Northern Railway is preparing as rapidly as possible to extend its coast line from Seattle south to Tacoma and Portland, and at the latter city it is to connect with the Southern Pacific for this city.

—Sixteen more miles of track will complete the line of the Santa Fe, Prescott & Phœnix Railway Company. It will be in operation in three weeks. The new road is 197 miles in length, extending from Ash Fork, via Prescott, to Phœnix, Arizona.

—The Pacific Coast Steamship Company has reduced freight rates between this port and Alaska from $11 to $3 per ton on general merchandise, subject to a further reduction to parties having freight contracts with the company, being the result of competition.

—President Palmer, of the Golden State and Miners' Iron Works, has finished the 300-H. P. engine, previously reported, which goes to the Casper Lumber Co., of Mendocino. The Works has also turned out a tandem compound engine for a stern-wheel steamer in Alaskan waters.

—The Felts Electric Light and Power Co. has incorporated. Principal place of business, Colusa. Capital stock, $1,000,000, with W. W. Felts, E. F. Pearl, G. T. Scott, J. K. Bartholomew, C. C. Felts, C. B. Harden, E. E. Scott, W. F. Ford, and U. W. Brown as directors.

—The Sacramento Electric Light and Power Co. have begun the erection of their pole line between Folsom and Sacramento. The first of the 1000-H. P. electric generators will be at the power house in Folsom about May 15th. The company expects to have the power in Sacramento and available for use by June 5th.

—The articles of incorporation of the San Francisco and San Joaquin Valley Railroad were filed this week. They provide for the construction of a railroad from a point on San Francisco Bay to Bakersfield, the distance being, approximately, 350 miles. The capital stock is set at $6,000,000, and $1,746,500, representing ten per cent of 17,465 shares, has already been subscribed.

—The first cargo of wheat that has gone around Cape Horn in thirty years, or since the transcontinental railroads monopolized the trade, has arrived in New York on the ship Reaper. It consists of 2000 tons, from Astoria, Or. The wheat will be sold at a loss, but the trip is due to the fact that the Reaper's cargo of barley was destroyed in the Portland fire of September '94, and the vessel had to take wheat instead.

The Union Gas Engine Co. has just shipped to the Margaritte Mining and Milling Co. a new form of sinking pump and gas engine combined. It is all self-contained and will be used in sinking a new 250-foot shaft on the mine.

—Grace & Co's chartered steamer the Bawumore is back form Talara Bay with 2500 tons crude oil. Captain Woodside reports having used liquid fuel all the way up, and found it satisfactory. The flues were clean, and there was no ash. The return trip was made in twenty days.

—On the Mexican International railway construction has commenced on the branch from Monclova west to the mining town of Sierra Mojada, about 160 miles. The line was partially graded in 1892. Work has also been commenced on the branch from Riata southeast to Monterey, sixty miles.

—The West Side Canal and Land Company has incorporated with a capital of $5,000,000, of which $25,000 have been subscribed. The purpose of the company is to irrigate Fresno, Kings, Merced and Stanislaus counties. Directors—William Strader, B. W. Gray, T. L. Orr, A. B. Dobbins and Wm. J. Smith.

—The Ontario Electric Company has incorporated with a capital stock of $100,000, of which $95,000 has been actually subscribed. Work will shortly be commenced on the Euclid-avenue electric railway, which will be seven miles long. Electric lights and a tower are also to be furnished by the new company.

—A syndicate of wealthy Chinese of this city, composed of members of the Six Companies, has secured a lease of the fruit ranch owned by General John Bidwell, the Chico millionaire. Bidwell's orchard was for many years the most extensive in the State, and still ranks second, containing between 4,000 and 5,000 acres planted in deciduous fruits.

—Governor Budd has appointed the following to act as commissioners for California at the Mexican International Exposition next year: Colonel A. Andrews, Irving Scott and James Cross of this city, Colonel H. Weinstock of Sacramento, S. J. Del Valle of Los Angeles, and Daniel Murphy Jr. of San Jose. These commissioners will act in conjunction with the local Mexican Consul.

—The bill which was introduced in the State Senate providing for the formation of a Sacramento Valley Drainage District, has been withdrawn, Senator Hart explains that he had introduced the bill as the request of Hon. A. H. Rose, Commissioner of Public Works, but had not agreed to support it. While he believed some plan of reclamation similar to that proposed by Mr. Rose would be adopted at a future time, he did not think the people were ready for it yet.

—The San Francisco and San Joaquin Coal Company has incorporated to purchase and deal in lands containing coal and coal deposits in the counties of Alemada and San Joaquin and elsewhere, to buy and build wharves, warehouses, etc.; manufacture lime; bore for natural gas and oil; to build, open and conduct hotels, stores; to manufacture machinery, and for various other business purposes. The directors are James Treadwell, John W. Coleman, J. D. Fry, J. C. Johnson, R. D. Fry and H. A. Williams. The capital stock is $5,000,000, of which $6,000 has been subscribed.

—Eight establishments submitted bids for the construction of the three torpedo boats authorized by Congress. The bid of the Union Iron Works was: department plan, one boat, $135,000; two boats, $129,000 each; three boats, $120,000 each; total, $360,000. Modified plan: one boat, $125,000; two boats, $120,000 each; three boats, $116,000 each; total, $348,000. Modified plan, larger boat, 240 tons displacement, and twenty-eight knots speed: one boat, $243,000. The Fulton Engineering and Shipbuilding Works bid: department plan, one boat, $148,000; two boats, $145,000 each. The boats must have a speed of 24.5 knots; there is no premium for extra speed, but there is a penalty of $10,000 per knot for failure to reach the requirement. "The department plan" is on plans furnished by the government: the "modified plan" is on plans submitted individually by the several bidders. It will be probably April 10th before it can be determined which is the bid to be accepted.

THE Mount Bischoff mine, in Tasmania, has paid over $6,000,000 in dividends.

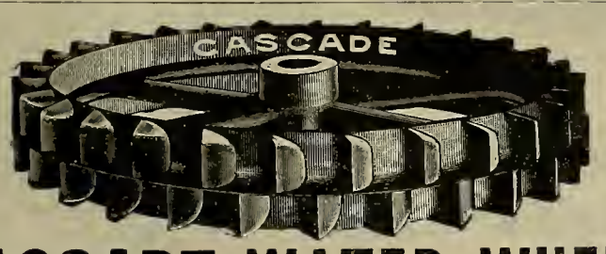
WATER WHEEL



CASCADE WATER WHEEL
Adapted to all heads, from 30 FEET TO 2000 FEET. Our experience of 33 YEARS in the water wheel business enables us to suit every requirement of water power plants. Send for illustrated pamphlet. This new wheel has given an unequaled Economy in Water.
JAMES LEFFEL & CO. Springfield, Ohio, U.S.A.

The Explorers' and Assayers' Companion.
By J. S. PHILLIPS, M. E.
A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying and Metallurgy.
The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay has been kept as free from formulæ as possible. The work is written for practical men, and all the explanations and discriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.
Price $6.00 postpaid. Sold by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

Books on Working Ores.
By GUIDO KUSTEL, M. E.
ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals Without Quicksilver. By GUIDO KUSTEL, M. E.
This rare book on the treatment of gold and silver ore without quicksilver is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, $3, postpaid. For sale by THE MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

GLADSTONE MINING COMPANY, FRENCH GULCH, Shasta Co., Cal.
C. J. Clark, M. E., Gen'l, Supt. Dec. 12, 1891.

MESSRS. ADAMS & CARTER, San Francisco, Cal.—DEAR SIRS: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the FRUE in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for TWELVE MONTHS. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to to mention. In order to give an idea of the work they are doing here, I will state that the ore has varied monthly from $5 to $20 per ton and the tailings from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six-foot Frue Vanner too highly, and it is the only table that I would have in my mill.
C. J. CLARK, Gen'l Supt.

MANUFACTURERS OF

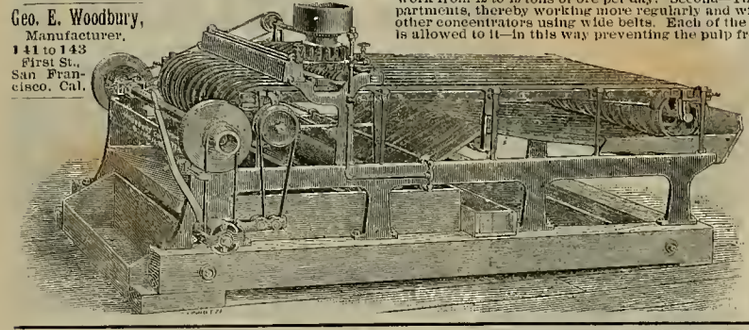
Johnston's Concentrator, Bryan Mills,
Challenge Ore Feeders, Air Compressors,

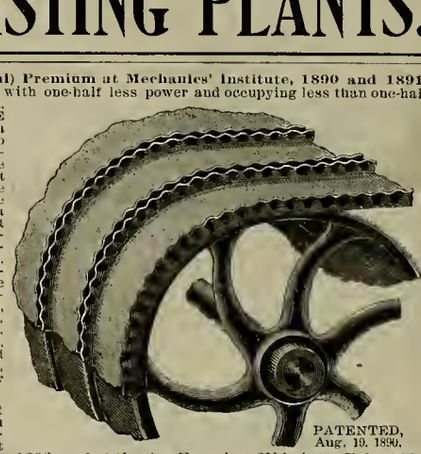
MINING, MILLING, PUMPING and HOISTING PLANTS.

THE WOODBURY ORE CONCENTRATOR WITH IMPROVED BELTS was awarded the Highest (Bronze Medal) Premium at Mechanics' Institute, 1890 and 1891. MORE THAN DOUBLE THIS CAPACITY with one-half less power and occupying less than one-half the space of any other concentrator. Built of best Steel and Wrought Iron. Strong and durable. **Price $575 f. o. b.** Send for Catalogue and Testimonials.

The annexed cut shows the belt in its improved form, which consists of corrugated edges, to form an expanding top edge. THE IMPROVED MACHINE HAS THE FOLLOWING MERITS: First—The Improved belts, which consist of seven, are constructed and arranged so as to allow each belt to receive a portion of the pulp in such a manner as to relieve the machine of its load, thereby giving it twice the capacity of other concentrators, and enabling it to work from 12 to 15 tons of ore per day. Second—The machine equalizes the load by several compartments, thereby working more regularly and with much less attention than is necessary to give other concentrators using wide belts. Each of the belts on this machine takes care of the pulp that is allowed to it—in this way preventing the pulp from running to the lower side of it, as is the case when a machine becomes out of level where wide belts are used. Third—The belts run on a perfect line, needing no adjustment to prevent their running from side to side, as in other concentrators. Fourth—The belt surfaces are improved by indentations and corrugations, causing the Concentrator to save fine sulphurets and quicksilver, and perform close work. Fifth—The belts have fluted or corrugated edges, to form an expanded top edge, which effectually prevents from cracking. Sixth—The feed arrangement is perfect. Seventh—The machine is constructed of iron, with steel crank-shaft self-oiling boxes, and everything made in the most thorough manner, enabling it to run with very little attention or wear.

Geo. E. Woodbury,
Manufacturer,
141 to 143
First St.,
San Francisco, Cal.





PATENTED, Aug. 19, 1890.

This Concentrator took the 1st prize at the San Francisco Mechanics' Institute in 1890, 1891 and 1892, and at the California State Fair in 1892; it took the 1st prize at the World's Columbian Exposition, 1893, and at the San Francisco Midwinter Fair, 1894

The McGlew Ore Concentrator Company.

PATENTED SEPTEMBER 19, 1893. **CHEAPEST, SIMPLEST, MOST DURABLE AND CLOSEST SAVING CONCENTRATOR IN USE.** FRANK BARRERE, Secretary and Manager.

Can be seen in operation at the Company's works, 132 Main Street, San Francisco.

Office, 116 Davis Street.

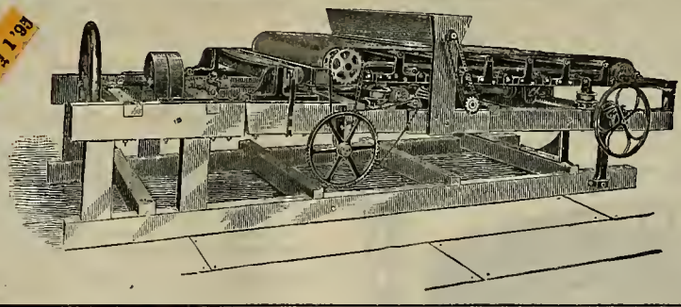
NINETY-FOUR AND ONE-HALF PER C[illegible]
—SAVED—
ON ORES DIFFICULT TO CONCE[illegible]TE.

A MARVEL of Simplicity, Durability and [illegible]ctiveness, combining both Side and End Motion [illegible] Bumping Belt.

SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILST IN OPERATION.

CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE.....$350 EACH
Including prepared canvas belt 4 ft. 6 ins. wide.



Cal State Library 1895

FALLS MINE, IGO, SHASTA CO., CAL., May 25th, 1893.

THE MCGLEW CONCENTRATOR COMPANY:—I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years' experience with different concentrators, I believed them to be the best.

Now, after a thorough trial of the McGlew Ore Concentrator, on ores difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ores. It is doing CLEANER and CLOSER work than I had believed possible for any concentrator to accomplish.

Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 94¾ per cent; from East ledge, * * * a saving of 92 per cent. The concentrator runs very easy and requires but slight attention. One man attends to rock breaker, crusher and concentrator.

You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily ecommend it to the mining public. Yours respectfully,
E. L. BALLOU, Propr. Ballou Reduction Works.

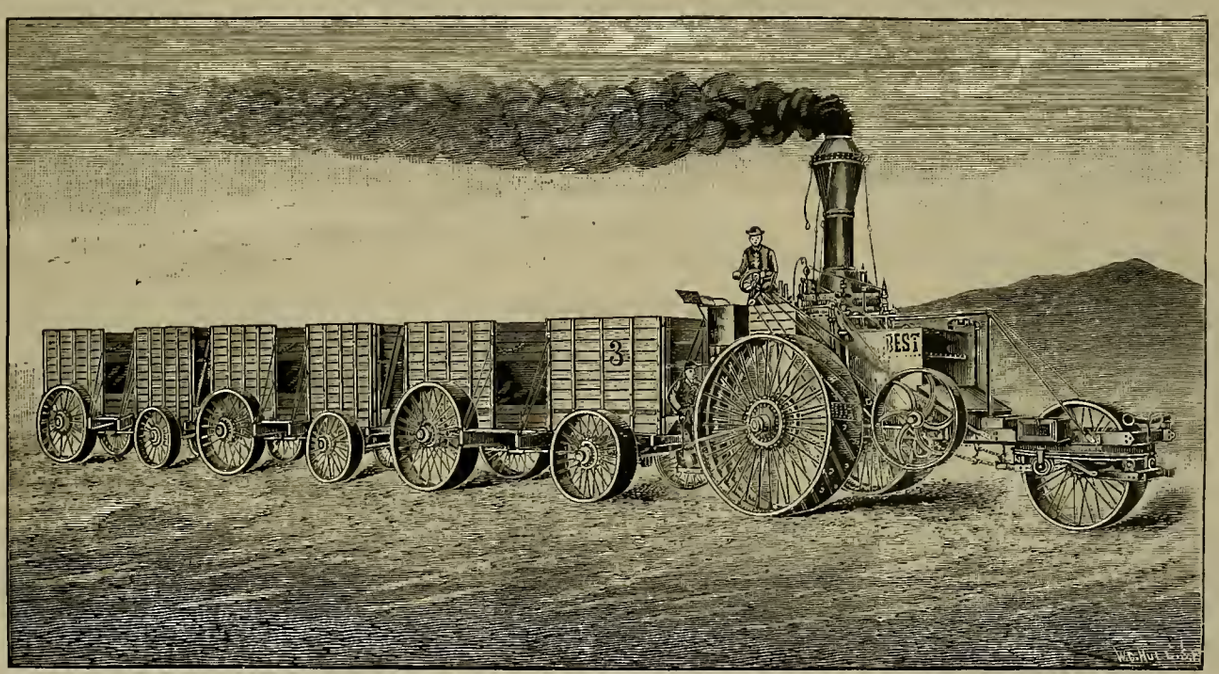
Traction Engine and Train for Steam Freighting.

At no work does a high-power traction engine show to better advantage than in steam freighting, which is now so extensively and profitably used in this State.

With suitable wagons, a reasonably good road, and with water and fuel stations properly located, the cost of moving grain, logs, lumber, coal, ore, etc., by the use of these wagons is not more than one-third as much as by the use of animal power.

The engine, as shown herewith, is of fifty-horse power, built by Daniel Best, of San Leandro, especially for steam freighting over any ordinarily good road. It can ascend and descend grades, as is practically done with horse or mule teams when in hauling freight.



TRACTION ENGINE AND WAGONS FOR HAULING FREIGHT.

These engines are capable of hauling twenty-five to forty tons, exclusive of weight of train, over grades of as much as 500 feet to the mile, and, in a pinch, much steeper grades; and on comparatively level roads the load may be increased fifteen tons or more.

This train is now in use in hauling salt a distance of thirty miles over the desert in San Bernardino county in this State, from the mines of the "Crystal Salt Co." to Danby, a point on the Atlantic and Pacific railroad, to be shipped to different points. This route is somewhat sandy; the train, however, makes the round trip (sixty miles) in one day and a half, including loading and unloading. The cargo averages about forty tons at each load.

That is a very trying place to operate a train, owing to the loose sand to be contended with and the scarcity of water for the engine—the water being hauled in sufficient quantity from one end of the road by the engine to supply it for the round trip.

However, the train is a success there and makes it possible to market one of the great resources of this State that otherwise would lie dormant for want of way of getting it to a shipping point on the railroad.

These engines are also extensively used in this State for hauliug logs to the mills and lumber to the market, some large firms owuing as many as three and four each, and at a profit considerably over animals which were formerly used by them, the engines doing the work much more satisfactorily.

As in the case of cable and electric roads and bicycles, it would seem that the raising of horses as beasts of burden is to dwindle as fast as the whale fisheries. Such machines as those herewith depicted will revolutionize land carriage. One Mendocino firm write that they have but two horses where two years ago they had 150. The lumber men "run up grades of 800 feet to the mile in going after logs. When they get to the point where they can go no farther without inconvenience, a horseman carries a light cable through the woods for a quarter of a mile if necessary and attaches it to a tree; then the engine on the wagon is set to work. It having a heavy cable and reel, it draws in the small cable, and in doing so the heavy one is paid out, and by the horseman attached to a log. Then the engine is set to work again and winds up the cable on the reel, and in doing so brings the log along with it. Then the engine is set to work again and loads the logs on the trucks, and so they build up fifty-ton loads and deliver them at the mill. They cut down no brush because they run over it. If a stump is in the way they simply take hold and pull it up and drag it out of the road."

In the great wheat fields of the State the traction engine finds as useful a place. By their use grain is cut and thrashed, aud sixty acres can be plowed in twenty-four hours. They will pump water, clear land, make roads, and will come in of use around a mine. "Say a railroad passes within thirty miles of a great mine. The traction wagon can go to the mine, making its own road, and can haul in at one time sixty tons of ore, aud all the expense is the little coal it burns and the labor of two men. It would bring sixty tons of ore thirty miles in seven hours. It could go to the mine, load the ore and bring it back between sun and sun, and, if necessary, could return and do the same thing over in the night, because it is not like an animal; it does not get tired; it is not particular about its food; all it wants is a little carbon in the shape of soft coal.". West Australian gold miners who depend on camels for freight are taking up this matter. D. W. Balch, now near Coolgardie, says these camels cost $250 at Fremantle. They carry about 700 pounds each, and can travel three miles an hour for eight hours. They require food and fifty pounds of water daily. On the route is employed 142 camels. The owners of the freight contract propose supplanting the camels by something similar to that herein illustrated.

CONSIDERABLE of our correspondence relates to "mining experts." Some of it is published, illustrating the general trend of opinion. The writer remembers twenty years ago fixing up, with the help of an assayer, a "specimen" and submittiug it to Prof. Frank Stewart, who gravely descanted ou the component parts thereof, and joined in the laugh on himself when its composition was told him. He was a "mining expert," but not infallible. Infallibility is an attribute ordinarily denied poor humanity in any walk of life. But because mining experts sometimes make mistakes; because a good many "mining experts" don't know anything more about mining than mining knows about them, it does not follow that the expert is to be condemned or derided. An experienced miner gifted with intelligent observation, with actual knowledge and careful speech, possessing an earned reputation for honesty, "unawed by influence and unbribed by gain," is not wholly an imaginary creation. Few mining transactions of any magnitude can be negotiated without the employment of what is deemed a reliable man, and the fact that the term "mining expert" is prostituted by numerous frauds should not justly detract from any individual who possesses the qualifications justifying him in claim to the title, though, in general, the real "mining expert" is in no haste to loudly proclaim his right to be so called.

THE newest thing in chemical attainment is acetylene—the commercial synthesis of hydrogeu and carbon. It is a veritable triumph, and was achieved hy means of the electric furnace. The carbide of calcium is an illuminant of the first class, and as a foundry factor it is of almost equal importance.

MISCELLANEOUS.—Concentrates, 147. California Scenery; Engineers Are Officers; Prices for Armor Plate, 148. Australian Gold; Building Guns More Cheaply; The Lightner Mill; In a Ton of Coal; The Curse of Official Endorsement; A Candid Concession; Wood in Warships; Ship Building Wages, 149. En Passant; A Sweeping Decision; Colorado Mining Stocks; Obituary; Recent Additions to the Collection of the State Mining Bureau, 150. The Mineral Hydrocarbons, 151. What a Man's Life is Worth; A New Launch, 157. Recent Patents, 158. Coast Industrial Notes, 159.

It is the province of every well-wisher of California mining interests to expose and oppose every fraudulent mining scheme wherever it shows up. One fraud hurts the county or district more than positive evidence of ten good claims can help it. Of course, the man or the paper doing this must expect to be abused and lied about, but eventually the truth will win.

Without any desire to deter determined men from going toward the Arctic circle in search of gold, it is in order to suggest to those who are contemplating departure to Alaska that the present cheap fares to Juneau should not too strongly influence them. It is pleasant as far as Juneau. Then the real journey and the real expense begins.

The form of industry whose latest development is illustrated by Scheunert et. al. cannot be commended. These enterprising men bonded a mine at Brown's Valley, incorporated, disposed of stock, and when the "innocent purchasers" of the stock, who claim to have believed that the issuers and sellers of the stock owned the mine, found such was not the case, trouble naturally resulted.

Twiggs' steam boiler inspection bill, which among other things provides for a corps of inspectors of the manufacture of stationary steam boilers in this State, may be good in its original intent, but it is believed, were it to become a law, that its practical working would be to put every manufacturer of such machinery at the mercy of men who could use their official position to extort money. The fact that steam engineers are expressly precluded from eligibility for members of the corps of inspectors makes the proposed law still more objectionable. It is a good bill to smother.

Both houses of the Legislature have passed the appropriation for the State Mining Bureau of $50,000 for the coming two years' expenses—sixty per cent of it being stipulated shall be devoted to field work. The bill only requires the signature of the Governor to be effective. He will in all probability sign it as a proper and deserved recognition of the miners and mining interests of California, in which direction the Bureau is doing much good and directing the attention of capitalists outside of the State to its mines. The Bureau will proceed with the publication of the several bulletins that have been held in abeyance pending the action of the Legislature. These bulletins will treat of the following subjects: Mine Drainage, Mine Ventilation, Mine Pumps, Method of Quarrying and Preparing Slate for Market, Electric Power for Hoists, Mill Drills, etc. The demand for the bulletins on Mine Timbering, Cyanide Process, etc., has been unprecedented and they have been of great value to the miners of the State.

The Newly-Found Constituent of Air.

"Argon," the newly-discovered constituent of the air, is the latest sensation in the scientific world. Two years ago Lord Rayleigh found that nitrogen obtained from the air is slightly heavier than that obtained from chemical substances. This fact led him to undertake experiments, in connection with Prof. Ramsey, on the nature of atmospheric nitrogen. In the course of their work they found that when the atmospheric nitrogen is passed over highly heated magnesium the nitrogen is absorbed, and still something is left. This residue will not combine with the magnesium, nor have they been able to make it combine with anything else.

They have devised several methods for the preparation of the substance, they have studied it with great care, and have established beyond any question, as it appears, that it is a substance which has not hitherto been known to exist. It is present in the air to the extent of somewhat less than one per cent. The substance is extremely inactive, and it is due to this fact that it was not discovered earlier. It has always been mixed with the nitrogen obtained from the atmosphere, and, being in some respects similar to nitrogen, it has escaped detection.

The name given to it, "argon," is formed from two Greek words signifying "no work," and referring, of course, to its inactivity.

The substance has been studied, not only by the discoverers, but also by Mr. Crookes, who is an authority in all matters pertaining to the spectroscope. The latter's conclusion is that argon is different from all other substances that have hitherto been studied, and he is somewhat inclined to believe that it is a mixture of two things, both of which are elements. Prof. Olszewski, of the University of Cracow, Russia, an authority on the liquefaction of gases, has determined the point at which argon liquefies, and has shown that it solidifies at an extremely low temperature, forming a mass that looks like ice. He thinks the substance an element and not a mixture.

Taking the sum total of evidence into consideration, it may be said that the balance seems to point to the conclusion that argon is an element.

Gold from Black Sands.

The usual number of new processes to successfully extract gold from black sand is reported. Recent research shows nearly a hundred different machines reported in these columns, many of them of theoretical merit, but scarcely one of sufficient practical value to continue in permanent and satisfactory use. The problem seems so far an unsolved one. The most recent efforts, each one being claimed to be successful, are reported from Oregon and Utah. The latter is purely a quicksilver process, the sand being forced twice through the mercury, with the alleged result of saving sufficient of the fine gold to make the operation profitable. Of this it may be said that if the projector secures success by the use of quicksilver, he has achieved results hitherto denied the most persistent operators in this line of practical metallurgy.

The second claim to the attention of the mining world comes from the north. Under date of February 20th, '95, the men owning and operating the system write to the PRESS:

"We have a chemical process of saving fine gold, and have thoroughly tested it in mining on this beach and on the bars of the Columbia river, and are ready to guarantee that we can save ninety-eight per cent of the free gold contained in any kind of sand or gravel, and wash with either fresh or salt water. We use no quicksilver and can demonstrate that we can save more gold by our system from the same gravel pit than any other process now in use, with the same labor and water. We are not the owners of any mines that are rich in auriferous gravel or sand, but have ground leased here. We save gold that would float away on the water by any other method, and no matter how rusty or greasy or fine the gold is we save it."

The claim that 98 per cent of the gold can be saved is a common one, and, in this case, is probably as much an exaggeration as heretofore. They say they use boxes charged with certain chemicals, costing from $1.50 to $2.50 per month to supply. If these gentlemen can anywhere near approximate their assertions in actual practice, they are to be congratulated. It is possible they have succeeded where so many have failed, and for every reason it is to be hoped that such is the case.

Dividend-Paying Mines.

The item "Dividend-Paying Mines" always makes interesting reading to Eastern people; yet, if they imagine that the published lists represent all the dividend-paying mines of the country, the information is misleading. The tabulated lists give only part of the incorporated company dividends, several of whom advertise the fact of having declared a dividend. But they do represent only a moiety of the mines that pay a dividend, or a profit, for a profit-paying mine is a dividend-paying mine, though some mines that declare dividends are not thoroughly profitable all around. It is impossible for this paper or any other paper to publish a correct list, or even an approximately correct list, of "dividend-paying mines," because, just as in any other branch of trade, the owners do not consider it is anybody's business but their own how much or how little their mine nets them. In this they are right, for no man cares to proclaim the profits of his business purely as a matter of current information, whether he run a mine or a store, a boat or a foundry, a sawmill or a factory. Mining people are no more reticent regarding their financial affairs than any other class. In general, any mine that represents an annual net sum after paying expenses is a dividend-paying mine, the same as any other business. In this way there are several thousand dividend-paying mines. "Up a hollow," or "over in the gulch," or "on the other side of the divide," may be found mines—quartz, drift and hydraulic—whose annual net output makes up the life of the vicinity. Their owners have no brass band; the aggregate yield is rarely seen in print, but the result is noticeable in the securing of the comforts of life, the acquisition of property, and the further development of the mine. These unnoticed mines are the real support of the country and of at least equal value with the much-advertised dividend-paying properties. Besides these are the mines that are yielding princely fortunes, the amounts of which are known to no one but the owners. The best-paying gold mine in this State to-day gives out no figures, but is generally credited with a daily net return of $7500.

Railroad Claims to Mineral Lands.

The famous "Clear List No. 54" has been exploited, and it has been shown that 133,590¼ acres in Sacramento and Susanville land districts are not to be allowed to pass without protest from miners owning unpatented claims therein.

There is another similar attempt at secrecy that needs ventilation. In a little paper in Scott valley appears the following innocent little notice:

TO WHOM IT MAY CONCERN: Notice is hereby given that the Central Pacific, (successor to the California & Oregon) R. R. Co., has filed in this office a list of lands, situated in the townships described below, and has applied for a patent for said lands; that the list is open to the public for inspection, and a copy thereof, by descriptive subdivisions, has been posted in a convenient place in this office for the inspection of all persons interested, and the public generally, viz: Townships 38, 39 and 40 north, range 8 west; townships 37, 39, 39 40, 45 and 46 north, range 9 west; and townships Nos. 37, 43, 44, 45, 46 and 47 north, range 10 west, Mount Diablo Meridian. Within the next sixty days following the date of this notice, protests, or contests against the claim of the railroad company to any tract or subdivision described on the list, on the ground that the same is more valuable for mineral than agricultural purposes, will be received and noted for report to the General Land Office at Washington, D. C. SYLVESTER HULL, Register. LAFAYETTE S. BARNES, Receiver.

That unpretending little paragraph covers, technically, all that the railroad company is obliged to do to absorb unpatented mineral land in fifteen townships in Trinity, Shasta and Siskiyou counties. Sixteen other townships come in the same category.

Every miner who has an unpatented claim in the territory referred to is interested in this matter. The time for filing a protest expires three weeks from to-day. Unless a miner visits the Redding Land Office and sees if the mining claim that he holds is within the limits set forth above, and if so makes protest against the issuance of title, he is liable to lose any right that he possesses and be compelled to make subsequent purchase from the railroad company.

Concentrates.

THE Alice mine in Riverside Co. started up last Monday on $20 ore.

AN electric plant is to be put in at the Eastlick mine, Siskiyou Co.

THE Hughes Creek placer property near Gibbonsville, Idaho, has been sold to St. Paul men for $30,000.

THE Supreme Court of Arizona has filed an opinion to the effect that ore on the damp is subject to taxation.

THE Grant & Omaha Reduction Works are reported contemplating the erection of a reduction plant at Guaymas.

C. L. YOUNG claims to have discovered a 40-foot ledge of cinnabar two miles from the Cleveland mine, near Davenport, Wash.

THE output from the leaching process at the Bi-Metallic mill at Granite, Montana, for January was 73,000 ounces of silver.

IT is reported from Georgetown, El Dorado Co., that a roller mill is about to be added to the Taylor mine plant; capacity, forty stamps.

PERRIS is pleased over the discovery of a gold mine in the Gavilan district, thought to be a continuation of the paying lead in that section.

H. A. HOWARD, now interested in the Cedros Island mines, has bonded several properties twenty miles east of Albuquerque for $200,000.

THE completion of the railroad from Asb Fork, on the A. & P. road, to Phœnix, Arizona, via Prescott, will give Phœnix "a boom" this summer.

THE Marysville *Appeal* asserts that the Anti-Debris Commission will shortly enjoin the North Bloomfield Mining Company from pursuing its mining operations.

THERE are seventy hydraulic mines in operation in Josephine county, Oregon, now, and the number will be greatly increased before opening up for another season.

THE property of the Eureka Mining Co., of Grass Valley, was recently sold at sheriff's sale in Nevada City to J. V. Hunter, formerly of the Providence Mining Co., for $13,739.97.

F. A. HEINZE has bought a half interest in the Rarus mine for $150,000. It is considered one of the best silver-copper properties in Butte. It is developed to the 600-foot level.

THE Calmalli Mining and Milling Company, operating the Ihura gold mines in Lower California, have put on the gasoline schooner Anita between San Francisco and San Domingo.

THE company that recently purchased the McHugh mine on Deer creek below the Home mine, Nevada Co., have a crew of men at work excavating a place upon which to erect a first-class mill.

THE California mineral land classification bill was one of the bills Congress did not pass before adjournment last Monday. The Montana bill passed and was signed by the President.

NONE of the bills introduced in the Oregon Legislature, affecting the mining industry of that State, passed. This is as it should be, as most of the measures proposed would have demoralized the industry.

THE steamship Willapa left Port Townsend on her first season trip last Monday for Alaska with eighty passengers. Every steamer going north is filled with miners and adventurers for the Yukon gold fields.

TWO MEN with the machine so long on exhibition at the Board of Trade rooms in this city are working the beach sands about six miles below the Cliff House, and, it is reported, are making from $5 to $15 per day.

FIRE in the No. 12 mine at Black Diamond, Wash., about 1300 feet from the surface, last Monday, gained such headway as to drive the men out. The head of the stope has been sealed, and steam is being forced into the mine to smother the fire.

BOSTON parties are negotiating for the sale of the Florence & Cripple Creek railway. The price to be paid is said to be $2,000,000. The line was built by Denver capital and cost over $1,000,000, and is paid for, the owners claiming not to owe a dollar.

COL. I. N. MUNCY, of Pasco, and later of Osburn and Columbia river fame, has again appeared on earth—this time on the Coquille river, near the dividing line between Oregon and California. He is working a sand bar near the mouth of the above river.

THE silver mines south of Nogales, in Sonora, are reported running in full blast, and hundreds of tons of ore pass through there every month, consigned to Colorado smelters for treatment. Most of the ore is rich in silver and carries a heavy per cent of lead.

THE coinage executed at the mints of the United States during the month of February was as follows: Gold, $6,143,800; silver, $391,000; minor coin, $57,300; total, $6,692,100. Of the silver coined $200 was in standard silver dollars, the same as during January.

FROM the Broken Hill Proprietary the report for the week ending February 14th says: 8570 tons of ore were treated, yielding 830 tons of lead, containing 218,980 ozs. of silver; also 1306 tons treated by amalgamating and leaching plants, producing 15,838 ozs. of silver.

THE American Developing and Mining Company will build a thirty-stamp gold mill on its property at Gibbonsville, Idaho. The mill is to be double discharge mortars for rapid crushing, the amalgamation being a secondary consideration. The ore is to be crushed to thirty mesh.

WITHIN a radius of twenty miles of Perris there are five mills, and forty-five stamps at work crushing ore. These do not include two prospectors' mills, rotary mills and arrastras, which cut quite a figure. Two years ago the section was scarcely known as a mineral district.

THE Pass Mining Company near Hailey, Idaho, are about to build a new concentrating mill upon ground owned by the Narrow Gauge Mining Company to have a daily capacity of fifty tons of ore that will yield about seven and one-half tons of concentrates. It will be operated by a gasoline engine and work automatically. The ore will be conveyed from the mine to the mill upon a gravity tramway that will bring down ore and haul up supplies and men.

THE Tombstone *Prospector* thinks it is of no use to expect English capitalists to go into mining in the West, or railroad building or manufacturing anywhere, when they can invest their money in American gold bonds and by a little manipulation get eight per cent profit out of them.

EX-MAYOR CHAPMAN, of Oakland, is credited with the statement that on his tract at the headwaters of Suisun bay lie huge deposits of gold-bearing sand which he is going to extract by electrical process. His theory is that the Sacramento has deposited gold there for many centuries.

THE Anaconda Company is negotiating for a hoisting engine that will be capable of raising the regulation weight from a depth of 5000 feet. It is to be placed on one of the hill properties belonging to the company. The contract for this colossal piece of machinery will not be closed for thirty days yet.

THE permit for the Hustler mine, Nevada county, has been suspended indefinitely by the California Debris Commissioners, the broken dam not being able to retain the debris. Permits were granted to the Shealor mine and the Kate Gray mine, near Volcano, Amador county, and the Fine Gold mine, near Vallecita, Calaveras county.

SAN DIEGO county is putting up sign posts in different parts of the desert in that county, which give directions as to distance and position of springs and principal places. If this were done on the Mojave desert several lives would be saved. The miner who risks his life in the search of mines, which are afterward a benefit to many, deserves such consideration.

CAPTAIN CARROLL recently purchased an interest in a mining claim on Annette Island, where the Metlakahtla Indians are located, and will commence development work upon the same next spring, although under strong protest from Rev. Duncan, who is afraid that contact with civilization will corrupt his charges.

THE American company which recently bought the Santo Domingo gold placers, in the Magdalena district, of Sonora, have already spent $100,000 in road-making, machinery purchases and other preliminary work. The ground to be exploited comprises 200 claims of a hectare each. The hydraulic method is to be employed.

WILLIAM WOODBURG, prospector, returned from a 900-mile trip from San Bernardino, ranging across the Mojave Desert to Death Valley and down through the San Jacinto mountains and across the Colorado desert. He located seven ledges. He says that in Pinon valley a two-stamp mill pounds out $4 an hour, some of the quartz yielding $1000 per ton in gold.

THE Senator Consolidated Gold Mining Company has under consideration a proposition to issue bonds and pay off the indebtedness of the company, amounting to nearly $10,000. *Mining Industry*, of Denver, speaks of the mine as one of the prettiest propositions in the country with which to fool a company, as the ore is rich on top and lower grade as depth is obtained.

THE success of the new reduction plants at and in the vicinity of Cripple Creek, for the handling of low-grade ores, is giving a market value to a class of material which heretofore has been unprofitable and either left in the mine or thrown on the dump, but which equals or exceeds in tonnage the high-grade or former shipping ores of the mines; this applies to all the low-grade ores of the gold mines of Colorado.

COL. CASEY killed the appropriation bill for the Cal. Debris Commission in his report to the River and Harbor Committee, wherein he said: "There was an unexpended balance on hand on January 31, 1895, for the purposes of this Commission, amounting to $7893. The expenses of the Commission from May 3, 1893, to January 31, 1895, amounted to $7107. I see no reason at present for making a special appropriation for the Commission."

THE new British Columbia mining law not only does not include the alien clause, but restores to the miner a privilege that he has long contended for, the surface right and timber privilege with each mining location. Heretofore the right to the surface has been denied to a British Columbia miner, even under a crown grant. A railroad could come along and cut off the trees and the miner would be obliged to go miles, sometimes, for timbers for his improvements.

THE Revenue mine in Madison county, Montana, one of the richest gold mines in the State, was sold last week by Butte parties to a Denver syndicate for $50,000, and, directly after the sale was perfected, it was announced that the Denver people had sold the mine to an English syndicate for $250,000. The mine originally belonged to Boston parties and was sold at sheriff's sale a year ago for $11,000. The mine has yielded handsome returns under a lease the past six months.

M. F. CAMPBELL, of the Gunsight mine, near the line of southern Arizona, says the camels of the desert, introduced many years ago by Ben Butterworth and now grown wild, are increasing rapidly, now numbering three or four hundred. The camels roam on lands between the Gila and Colorado rivers. They are kept in good condition by the fine bunch grass, and are often killed and palmed off for beef. They are often captured for circus purposes, and are easily trained.

THE Cœur d'Alene *Miner* says that the reported sale of the Tiger and Poormau mines to an English syndicate is utterly without foundation. Negotiations have been pending for many months between the owners of the four principal mines on Canyon creek and the English syndicate in question, but about two months ago, says Mr. Clark, manager of the Poorman, they came to an end simply because the terms of sale of the properties could not be agreed upon by all concerned.

THERE has been presented to the Academy of Sciences, in this city, a fine collection of Japanese rock crystals, consisting of many beautiful specimens in various shapes. Some are beautifully carved in fantastic designs. The gem of the collection is a large crystal sphere, seven inches in diameter. An idea of the immense power of the crystal can be formed when it is understood that, if the rays of the sun were focused through it on gunpowder, an explosion would occur in the fiftieth part of a second.

THE new Montana mining code makes some changes in the method of making quartz and placer locations. A shaft or tunnel ten feet deep must be dug before the location notice can be recorded; this shaft must always reach to solid formation. The time for recording is extended to ninety days after locating instead of twenty days, as at present. In case of relocation, if the old discovery is used, it must be sank ten feet deeper. A new provision is that the locator may, if he desires, have a United States depaty mineral surveyor make a survey of the claim before location notice is recorded, and, if the field notes of the survey are attached to the recorded notice, they are prima facie evidence of the truth of the matters contained therein.

AT 5:48 last Sunday morning an immense aerolite shot out of the northern heavens and seemingly passed over Reno, Nev. It exploded with terrific force, shaking buildings and awakening people. Those who saw it describe it as a magnificent sight, lighting up the heavens and earth in all directions. It was accompanied by a whirring noise, like a tornado. The people on the street involuntarily dodged. It was probably at a great distance, as the explosion "was not heard for two minutes after it dropped."

THE Debris Commission last week gave permission to the following persons to operate hydraulic mines: James Slater, mine near Brownsville, in Yuba county; Giani D. Martini and others, Railroad Hill mine, near Fort Crossing, in Calaveras county; George H. Poase and J. H. Colwell, North Rim mine, near Yankee Jim's, in Placer county, the applicants having agreed to construct dams to bar the exit of debris or to use dams adjoining the mines. About twenty more applications are to be considered.

IN order to make room for minerals, several of the noted objects of the museum of the Mining Bureau on Fourth street in this city are being sent out to the Golden Gate Park museum, viz: The marble figure of Rebecca at the well, belonging to J. Z. Davis; the Egyptian mummy has also gone to the park for a more salubrious atmosphere; the baboon that has so long grinned at Rebecca from his glass case that he now misses her society, will soon follow, as will several more large objects that occupy space which will hereafter be devoted to additional minerals.

THERE is now being advertised in the Redding *Democrat* land claimed by the railroad, and unless action is taken in the shape of a protest by the 30th inst., patents will issue, notwithstanding that it comprises a large amount of mineral land. Five townships are in Trinity Co.—townships 34 and 35 N., R. 7 W., 31 and 33 N., R. 8 W., and 32 N., R. 9 W. The fact that the land is mineral makes no difference. The miners interested should file a protest at Redding before the 30th, or expect, unless they already have patented claims, to be called upon to get title from the railroad company later on.

LOCATION NOTICES written in lead pencil last longer than those written in ink. A notice written in ink, and posted at a mining location on paper, will last about one year, while a pencil notice will last as long and be as plain as the paper upon which it is written and will stand the elements of the weather. A notice written on a board or the smooth side of a stake in pencil has been known to last for fifteen years. For some reason or other a notice written in ink soon becomes obliterated by snows and stormy weather and is soon unintelligible, while pencil writing is not defaceable by anything other than intentional destruction.

IN Missouri in '94 the average price of zinc ore was $5.57 per ton less than in '93, while the price of lead dropped $1.86 per ton. Lead and zinc ore is produced in ten counties in that State and in all 563 shafts are operated. The number of tons of lead ore mined during the year was 52,003, valued at $1,949,568, and of zinc ore, 89,150 tons, valued at $1,337,910, making a total for the two of $3,287,478. The average price per ton paid for zinc ore was $15, and for lead ore, $37,48. There were 5065 men employed during the year, of which 3421 were miners. Seventeen miners were killed during the year and twenty-nine non-fatal accidents occurred.

IN a decision on appeal of the Silver King Mining Company, from the Secretary of the Interior, it is decided that a certified copy of the certificate of incorporation of a mining company is sufficient to file with an application for patent, and not a copy of the articles of incorporation. The Commissioner of the General Land Office has been in the habit of calling for copies of such articles from time to time, in the face of the law, thus putting applicants to much useless delay and expense. Copies of such articles generally cost from $10 to $15, whereas the copy of a certificate of incorporation only costs $1.50. This decision settles the point definitely.

A MELBOURNE, AUSTRALIA, paper tells a story about Coolgardie which may not be true. A party struck it very rich, and one of their number was dispatched to London with the specimens, upon the strength of which a company was floated with a large capital, a fine slice of which went to the vendors. The legal managers telegraphed out to the man in charge to start crushing at once. He waited patiently for results, but received no reply. Several times he wired to the same effect, with no better results. Then he sent a more urgent message, as follows: "Shareholders indignant that no report received from you. Acknowledge this, and commence crushing immediately." This elicited a reply, as follows: "Your wires duly received. Cannot commence crushing till you send back the reef."

A GOOD DEAL is said in mining items from the Slocan country, B. C., about "rawhiding" ore and other freight. The "rawhiders" take cowhides just as they are skinned from the slaughtered animal. Any rough edges may be trimmed off. Holes about one inch in diameter are cut about one foot apart around the edges, the hide is laid flat on the ground and the sacks of ore piled thereon. Some rawhiders place two sacks side by side and some three. After the hide is loaded the ends and sides are drawn together by a rope passed through the holes as described above. In this manner the load is laced tightly in the hide. The neck of the hide is always the front and to it is fastened the whiffletree. If the trail is very steep, one or more loads of sacked ore are hitched one behind the other and the mule started down the trail on the run. For extra steep pitches in the trail a rough lock, consisting of a steel chain, is fastened around the load. All supplies for the miners are hauled up the trail by rawhide transportation. So expert do the rawhiders become that they balance themselves standing on top a loaded hide while the mule is going down a steep mountain side on the dead run. The mules themselves soon learn where to stop for the rough lock to be applied, and it is said by various chroniclers of the Slocan that some rawhiders have their mules so well trained that they sit down on the load and shoot over the steepest places, thus making rough locking unnecessary.

California Scenery.

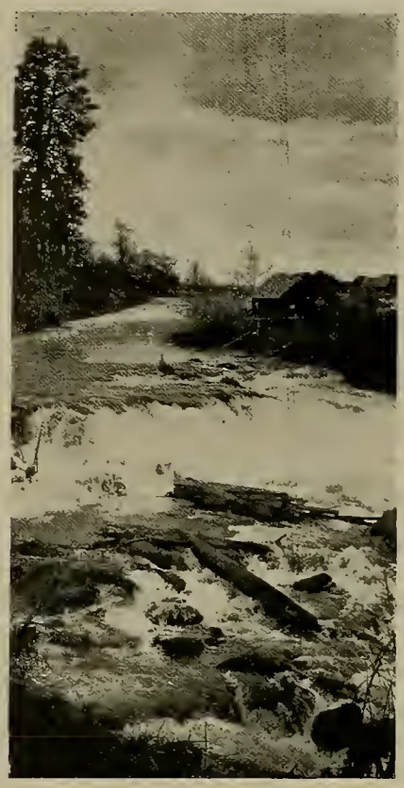
The engravings on this page display two widely different features of Pacific coast scenery. One is of Fall river—a mountain stream in the extreme north—which pours its waters into Pitt river and thus makes its contribution to our great Sacramento. An appreciative writer speaks of its region in these words:

"Fifty miles southeast from the upper McCloud Falls, across measureless earthquake upheavals, traversed in midwinter on snowshoes, the road steeply descends into Fall River valley. A serene panorama of vernal plain and slow-creeping rivers greets the eye restfully after the exciting exaggeration of mountain landscape beheld for a fortnight. To the right, beyond leagues of bright meadow, a cluster of lakelets bubble out of the loose lava crust which covers the northeastern corner of California. These small, brimming basins are the terminal flowers of branching stems of the Fall, Bear and Tule rivers. Fall river is the longest in view, dropping its unrippled coils down an emerald space of valley until, coming suddenly upon the dark, sluggish Pitt, it leaps to that sullen current in a delirious frenzy of shrilling, foaming cascades. The quickening is instantaneous. The Pitt is transformed into a roaring torrent, speeding straight for an austere line of ashen cliffs."

That treats of Fall river in its wilder aspects. The photographer whose view we present caught it in its milder moods, where it turns mills and ministers to the service of cultivation.

The other engraving on this page presents another river scene in central California. The hard, smooth roadway amid rocks and trees and wooded slopes, with vistas of the river below, suggest to the denizen of coast or valley the pleasures of summering in these higher altitudes. The river in this case is the Tuolumne, as it leaves that county's borders; but the view is merely typical of hundreds in the foothills of the Sierra Nevada on the California side, and all who have enjoyed them will find their impressions reflected in these lines of one who evidently appreciates such scenes:

"The landscape spread before us always was, from an artistic point of view, beautiful. Continually we get glimpses of the distant Sierra covered well with snow, and the effect upon the more quiet aspect of the near landscape was to lend a feeling of expanse and dignity to it all, which is scarcely to be conveyed by words. There is a sense of vastness about all California landscape which takes quiet possession of an appreciative beholder, in a way that is somewhat remarkable. The long, dry summers fill our air with a tremulous, lilac-toned haze that gives an air of mystery and distance which I have never seen in any other land. This is aided by the openness of the skies day by day, their rich, warm blue and violet tones only accented by an occasional streak or tuft of wandering cloud that appears to be at an immense distance aloft. The eye wanders over a vast wealth of detail in hill, mountain and woodland, diversified by a great variety of tree growth and flora."



SCENE ON FALL RIVER.

A GLIMPSE OF THE TUOLUMNE RIVER.

Prices for Armor Plate.

The prices paid for armor plate, according to a recent communication of the Secretary of the Navy to the United States Senate, are as follows: For American ordinary armor plate, $500 to $575 per ton; for "special" armor, $600 to $725; cost of treating by Harvey process, $61.60 per ton additional. The "compound" armor, purchased at Sheffield, England, for the Miantonomoh, is said to have cost $535 per ton. The nickel-steel armor made in the United States contains 3.25 per cent of nickel; that made abroad contains from 2 to 2.25 per cent. The Secretary calls attention to the fact that foreign armor is made in various grades and of various prices, and that the bids of English and French armor manufacturers for armor for foreign use are much lower than for armor for ships of their own nationality. The contracts with the United States makers are more severe in many respects in their requirements for acceptance than those abroad.

Engineers Are Officers.

Geo. W. Melville, Engineer-in-Chief of the U. S. Navy, has this to say on the mooted question of the right of engineers to the title of "officer":

The *Century Dictionary*, regarded as the best modern authority on the meaning of words, defines an officer to be "One who holds an office, or to whom has been intrusted a share in the management or direction of some business or undertaking, such as a society, corporation, company, etc., or who fills some position involving responsibility, to which he has been formally appointed." Is, or is not, the engineer of a steamship an officer within the meaning of this definition? His position unquestionably fulfills both of the requirements of the definition, for he is certainly intrusted with a share in the management of the undertaking, i. e., the steamer, and in the second place, no one who has ever been on board a steamer at sea can deny that the engineer's position does not involve responsibility.

The claim of the deck, or sailor, officer to being an officer is based upon inheritance from a condition of things now obsolete rather than upon any real importance or responsibility involved in his present position. In olden times, and on sailing vessels to-day, the master and mates held a position of serious responsibility, and were charged with the sole management of their ships, but that condition does not now exist on the steamers that are now engaged in carrying on the world's commerce. The finest example of modern steamships, notably the Atlantic "greyhounds," and the swift mail steamers of the East India trade, are absolutely without sail power, and even without masts, except for signaling purposes, a development that has removed a heavy load of responsibility from the deck officer, and has reduced him in practice to the status of a watchman or lookout. He no longer has to scan the horizon in fear of being knocked down by a sudden squall, nor is he required to be constantly vigilant and worried lest the change in the wind or an unequal press of canvas bring his masts and spars down about his head, possibly to the peril of the ship itself. Beating through a crowded harbor, clawing off a lee shore in a gale, or skillfully bracing his yards to avoid collision, are all dangers and cares from which he is relieved, and of which he may have no knowledge except that acquired by reading old sea tales. In this day of steam, the engine-room telegraph is his panacea for all troubles, and if he knows how to throw its pointer in the right direction, another more responsible than himself comes to the rescue. Literally, he touches the button and the engineer does the rest. Instead of nervously and carefully watching the rigging and spars and the ship's course, his responsibilities are now reduced to an occasional admonition to the man at the wheel, and to keeping a lookout ahead. If he sees a vessel, iceberg, or other obstacle in his path, he rings the engine-room bell and is safe. A pilot takes him in and out of port, and is responsible while on board.

On the other hand, the responsibility which once haunted the watcher on deck has now found a place below, and the engineer goes through his watch oppressed with a load of cares fully as heavy as that once borne by the deck officer. Instead of overpressed sails and bending masts, he has to regard a battery of huge boilers, each charged almost to distortion with a tremendous pressure of steam, and each in itself a magazine whose explosion would rend the ship in pieces, and a set of great engines equally overcharged and carry on them a multitude of details infinitely more complex and vital than ever was the network of rigging by which the sailing ship was controlled. I remember seeing in print once a letter from a sailor officer, sadly deseanting upon the decadence of the times and announcing, with a show of anger, that the claim of the new-comers to the rank of officers was an insult to the "sea profession." The "sea profession," indeed! What is it at this close of the nineteenth century, but marine engineering!

A SATISFACTORY balance to the credit of the Patent Office appears in the annual report of that branch of the Government for the year 1894. The excess of receipts over expenditures for the year amounted to $87,392, which, added to the amount of previous balances, shows a total of $4,369,135. During the year 36,987 applications for patents were received and 20,803 patents were granted. It appears that in proportion to population more patents were issued to citizens of Connecticut than to those of any other State—one to every 993 inhabitants; and next in order came Massachusetts, with one to every 1335 inhabitants, and the District of Columbia, with one to every 1379 inhabitants. New Jersey, Montana, Rhode Island, New York and Colorado followed in the order named. The smallest number of patents in proportion to the number of inhabitants were issued to citizens of South Carolina, Mississippi, North Carolina, Arkansas and Georgia, following in that order.

A PECULIAR fatality is reported from the East Norrie iron mine, near Ironwood, Mich. The mine is lighted by electricity, and the wires are usually carried through iron pipes. A timberman named Jacobson, while working in a shaft, sat on one of these conduits, and placing his hands on the conduit, received a shock causing his instant death.—American Gas Light and Coal Journal, Feb. 16th.

GOLD is coming into the mint from mines of this State at the rate of a million dollars a month.

Australian Gold.

D. W. Balch, formerly a well-known Comstock assayer, is now among the Australian gold fields. In a letter written from Sydney, N. S. W., to an old friend in Virginia, Mr. Balch describes the prospects and methods of that country in a highly interesting manner. The letter in part is as follows:

"Bratnover and Callighan were sent out here by an English mining gang and they have been out to Murchison, Coolgardie way, for the past three months, but are here now. They speak well of the country, but say that at present they ask too much for their claims; besides, just at present it is very hot and sickly there. They both say they never saw such a country for ledges—there are thousands of them. Some of them stand up from twenty to fifty feet high. Some of them are very remarkable for their phenomenal richness.

"There is a man here in the city now by the name of Mills who found the Londondery. It was sold the other day for $900,000. He got $300,000 as his share. He is an Irishman, who never mined before in his life, can't read or write, but they say is quite shrewd. All the old prospectors warned them not to go where they did, as they knew there was nothing there. As they were all dead broke and could not get away from Coolgardie, they had to prospect within a mile of the city. I don't know how much they took out in a few days, but it was a very large amount. As they could not agree about working the mine, none of them ever having mined, they sold the claim.

"New finds are being made all the time, and now the prospectors are in places 100 miles from Coolgardie. The country is without water, except salt lakes, and the water in the shafts is brackish when found. Condensers are run all over the country, and the whole country is covered with a thick low brush, called "mallee scrub." People are getting lost all the time, and you hardly take up a paper without reading of some one being lost in the brush. The country is all gold bearing from the Murchison to Coolgardie, 500 miles, and it is thought it will take five or ten years to prospect it. In fact, they have not yet begun to prospect Australia, as gold is found all around the continent—8000 miles—and they have only prospected about 500 miles in from the coast.

"All around it leaves about 1200 miles of unprospected country in the interior. I had always thought that the interior was a sand desert, but such is not the case. Very few sand deserts are in the country, but the interior is covered with this dense scrub and water holes are scarce; but all over the country water can be found by digging wells from 30 to 200 feet deep. As a sample of what is in the interior and at present undeveloped, I heard of a prospecting party of ten, with eleven camels, which left Adelaide, Southern Australia, about a year ago. They paid out $7500 and brought back 400 ounces of gold that they knocked off ledges that they found.

"All the mines that have been sold so far at Coolgardie have been sold on their report. From what I can hear I think this excitement will keep up for a long time yet, as all persons who come back that know anything about mines agree that the country is good, but it will take lots of money to develop it. It is time to go there in a year or so from now. It is about 3000 miles from Coolgardie to here, 2500 by steamer to Fremantle and 500 from there by rail and stage. Go as fast as you can and it takes over two weeks to get there and costs all of £100."

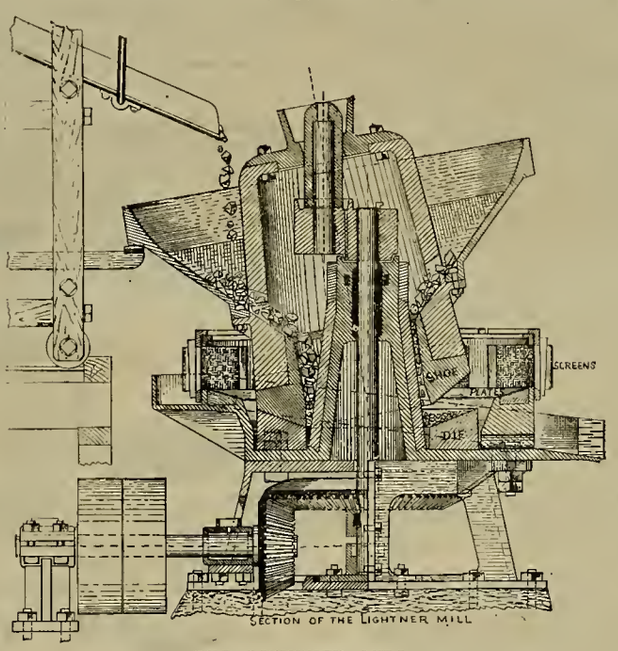
Building Guns More Cheaply.

The very heavy cost of modern guns is largely due to the time and labor which are necessarily expended upon the operation of rifling them. The material itself is relatively cheap, and a rifled gun, besides being much more costly, is, other things being equal, more short lived than a smoothbore. It is almost impossible so to make the gun and the projectile that the soft driving bands of the latter shall, at the moment of discharge, accurately fit into the grooves and lands of the bore and allow no gases to pass ahead. When these gases do pass ahead of the projectile, they score and damage the interior of the gun, and where the new powders are used and the gases of combustion attain an enormous degree of heat, the process of deterioration, especially in weapons of large caliber, is often very rapid.

A Swedish engineer, W. T. Unge, has devised a method whereby he hopes to save not only the cost of rifling, but also the interior wear and tear for which rifling is responsible. He proposes to construct all guns with smoothbores and to fit the projectiles with gas checks, which shall render it practically impossible for any gases to rush past them. In order to convey to the projectile an axially rotary motion, such as is at present conveyed to it by the action of the rifling, he has invented a mechanical arrangement which, at the instant of firing, gives to the gun itself the rotary motion. This may be either constant or increased. He has satisfied himself that the effect upon the projectile is exactly the same as is produced by the constant or increasing twist of an ordinary rifled gun, and he is of opinion that the adoption of his system, while giving equal or even improved accuracy of fire, will reduce the cost of heavy guns by one-half and add enormously to their endurance.

The Lightner Mill.

The Lightner quartz crushing and grinding mill is herewith illustrated, giving a sectional view. The operation of the mill is as follows: The rock is fed from an automatic ore feeder into the hopper which surrounds the gyrating muller, from which it passes through ports or holes to the inside of the muller, where it is crushed between the muller and the central cone in the mortar, then, dropping to the bottom of the muller, is ground between the muller shoe and die in the mortar. The water is fed in with the rock and flows from the center, carrying the finely ground materials with it towards the discharge screens, which are all around the outside of the mortar. The motion of the muller causes a strong wave-like splash against the screens, securing a quick discharge. Amalgamating plates are secured on the slope between the die and the discharge, and the peculiar motion of the pulp, washing to and fro over the



THE LIGHTNER MILL.

plates, makes the mill a first-class amalgamator. In addition to the gyrating motion, the muller has a rotary traveling motion and a side-slip radial motion on the die. These mills run at a speed of from 80 to 130 or more revolutions per minute and will work any kind of hard rock or dirt, to any degree of fineness, depending on the screens.

The advantages claimed are: Cheapness of first cost and operation, slight cost of wearing parts, slight cost of future maintenance, slight wear of metal to quantity of rock crushed, ease with which it can be cleaned up; automatic feed can be applied; no large rocks can be thrown against screens; two places requiring oil; quick discharge, preventing sliming; the large percentage of gold saved in the mortar, making an extreme area of outside plates unnecessary; damage to mill impossible from increase of speed; no oil can reach pulp; requires very little power to drive mill.

In a Ton of Coal.

From one ton of ordinary gas coal may be produced 1500 pounds of coke, 20 gallons of ammonia water and 140 pounds of coal tar. By destructive distillation the coal tar will yield 69.6 pounds of pitch, 17 pounds of creosote, 14 pounds of heavy oils, 9.5 pounds of naphtha yellow, 6.3 pounds of naphthaline, 4.75 pounds of naphthol, 2.25 pounds of solvent naphtha, 1.5 pounds of phenol, 1.2 pounds of aurine, 1.1 pounds of benzine, 1.1 pounds of analine, 0.77 of a pound of toludine, 0.46 of a pound of anthracine and 0.9 of a pound of toluene.

From the latter is obtained the new substance known as saccharine, which is 530 times as sweet as the best cane sugar, one part of it giving a very sweet taste to a thousand parts of water.

The Curse of Official Indorsement.

If there is any one thing which public officials of all classes should avoid, in their capacity as officers, it is the practice of indorsing certain enterprises and schemes. Many a wildcat financial scheme has been foisted on the public through the intentional or unintentional indorsement of some man holding a public office.

Men with fertile brains will incorporate some investment or other kind of company, and the first thing they do is to get the indorsement of some man in public life. This is often done by securing his name as a stockholder, which is done by presenting him with a few shares of the stock. With this apparent indorsement they sally forth and soon the public is persuaded to invest in the new concern, one of the great arguments used being that Mr. So-and-so, high in official circles, has enough confidence in it to take stock.

Men in public life, it matters not what position they occupy, owe a duty to the people they represent, and when they, intentionally or unintentionally, lend their names to enterprises which they do not know to be absolutely legitimate, they are certainly derelict as public officials.—The Investor.

A Candid Concession.

"Can Americans tin their own plates now?" was the significant inquiry recently made by a reporter of one of the Welsh newspapers to T. Phillips, secretary of the Welsh Tin Makers' Association. "Yes," was the reply. "They manage all the processes. On the other side of the Atlantic they are apparently laying down heavy machinery. For example, their standards in the mills weigh thirteen tons as compared with four tons in Wales. Evidently they think it will pay to have the machinery well laid down." Here in truth is testimony to the superior design of American tin-plate rolling mills out of the mouth of a Welsh official which deserves to be recorded, and upon which American makers may fairly flatter themselves without laying themselves open to any of the charges of boasting which Britishers are still so fond of bringing against transatlantic cousins. "What do you think, Mr. Phillips, is the prospect of the future manufacture of tin plates in America?" was the interviewer's next inquiry. "The Yankee will probably make 2,000,000 boxes and then he will stop and look around to see what profit he has made," was the answer of this master's secretary.

Wood in War Ships.

The board convened by Secretary Herbert to consider the subject of dispensing with wood in the construction of the naval ships now building, and also for the purpose of finding some suitable substitute for wood in places where it is impracticable to use metal, of which board Commander Bradford is senior member, is said by the Philadelphia *Ledger* to be making fair progress. Since the naval action fought off the mouth of the Yalu river between the Chinese and the Japanese fleets, during which several ships were disabled and thrown out of action by serious fires on board, the matter has received much attention at home and abroad. The German admiralty has convened a board to find some proper substitute for wood. In the meantime the use of wood has ceased altogether, even the furniture being made of iron, and cork used where a non-conductor is absolutely necessary. The English have not yet taken any definite action, but are casting about for some substitute for wood. The French have for a long time used a minimum of wood, and in all foreign ships less wood has probably been used than in those of our service.

Ship Building Wages.

C. H. Cramp gives the following comparative table of current wages here and in Great Britain in shipbuilding:

	United States, per week.	*Great Britain, per week.*
Pattern makers	$18 00	$9 00
Machinists	15 00	8 50
Boiler makers	15 00	8 50 to 9 00
Clippers and calkers	15 00	7 80
Riveters	12 00 to 14 00	7 50 to 8 00
Beam and angle smiths	15 00	8 40
Fitters up	15 00	7 80
Ship carpenters	18 00	9 60
Joiners	16 50	9 00
Painters	18 00	9 60
Coppersmiths	18 00	8 60 to 9 00
Shipshed machinemen	15 00	7 20
Furnacemen	11 00	6 00
Holders on	9 00	4 20 to 4 80
Riggers	11 00	7 00 to 7 20
Plumbers	18 00 to 19 00	9 00 to 9 60
Drillers	11 00	6 40
Sheet iron workers	15 00	8 50
Molders, iron	14 50	9 00
Molders, brass	15 00	9 00
Laborers, as helpers	9 00	5 20
Laborers, as handlers	8 00	4 20

COBALT NITRATE is found by Dr. Johann Antal, a chemist of Hungary, to be an antidote to prussic acid and cyanide poisoning. First he tried the cobalt on animals, and then, presumably at different times, on forty living persons who had been accidentally poisoned by prussic acid, and in all cases the results are reported to have been satisfactory.

The Mineral Hydrocarbons.

Their History, Geography, Geology, Physical and Chemical Properties and Uses.

NUMBER XXIV.

Written for the MINING AND SCIENTIFIC PRESS and copyrighted 1894, by Henry G. Hanks, F. G. S.

Sir William Hamilton mentions the lake Mare Morto, Fol. 150, near Point of Misenum. "Under the ruins of an ancient buildiug, in a vault, there is a vapor or 'mosete' exactly similar in its effects to that of the Grotto del Cane, as I have often experienced." Referring to Mount Ætna, he says: "A very powerful mosete has recently manifested itself in the neighborhood of Ætua, and near the spot whence it rises animals, birds and insects are found dead, and the stronger sort of shrubs blasted." (Fol. 166, Observations on Mount Vesuvius, 1782).

In a paper read before the Royal Society, Jan. 15, 1795, the same anthor treats more fully the subject of "mephitic vapors," from which the following are extracts: "After every eruption of Vesuvius we read of damage done by mephitic vapors, which, coming from under the ancieut lavas, insinnates itself into such low places as cellars and wells of houses situated at the foot of the volcauo. After the eruption of 1767 I remember that there were several instauces, as in this: of people going iuto cellars as in Portici and other parts of that neighborhood, having been struck down by this vapor and would have expired had they not been hastily removed. These occasional vapors, and which are here called 'mosete,' are of the same quality as that permanent one in the Grotto del Cane, near the lake of Agnano, aud which has been proved to be chiefly fixed air (carbonic acid gas) (Fol. 106).

"The vapors which in the volcanic language of the country are called 'fumaroli' are of another nature, aud issue from spots all over the fresh and hot lavas while they are cooling. They are sulphurous and suffocating, so much so that birds that are flying over them are overpowered and fall down dead. * * * The first appearauce of the mosete after the late eruption was on the 17th of June, when a peasant, going with an ass to his viueyard, a little above the village of Resina, in a narrow way, the ass dropped down and seemed to be expiring. The peasant was soou sensible of the mephitic vapors himself, and well knowing its fatal effects, dragged the animal out of its influeuce and it soon recovered. From that time these vapors have greatly increased and extended themselves. There are to this day many cellars aud wells all the way from Portici to Torre del Annunziata greatly affected by them.

"This heavy vapor, when exposed to the open air, does not rise much above a foot from the surface of the earth, but wheu it gets into confined places like a cellar or well it rises and fills them as any other fluid would do. Having filled a well, it rises above it about a foot, aud then, bending over, falls to the earth, on which it spreads, always possessing its usual level.

"Wherever this vapor issues a wavering in the air is perceptible like that which is produced by the burning of charcoal, and when it issues from a fissure near any plants or vegetables the leaves of those plants are seen to move as if they were agitated by a gentle wind.

"It is extraordinary that, although there does not appear to be any poisonous quality in this vapor, which in every respect resembles fixed air, it should prove so very fatal to the vineyards, some thousauds of acres of which have been destroyed by it since the last eruption. When it penetrates to the roots of the vines it dries them up aud kills the plants.

"A peasaut in the ueighborhood of Resina, having suffered by the mosete, which destroyed his viueyards in the year 1767, and having observed that the vapors followed the laws of all fluids, made a narrow, deep ditch all around his vineyard which communicated with ancient lavas, and also a deep cavern under one of them. The consequence of his well reasoned operation has been that, although surrounded at present by these noxious vapors which lie constautly at the bottom of his ditch, they have never entered his vineyard and his vines are now iu a flourishing state, while those of his neighbors are perishing. Upward of thirteen hundred hares and many pheasants and partridges, overtaken by this vapor, have been found dead within his Siciliau Majesty's reserves, aud also many domestic cats, which, in their pursuit of game, fell victims to the mosete.

"A few days ago a shoal of fish of several hundred pounds weight, having beeu observed by some fishermen at Resina in great agitatiou on the surface of the sea near some rocks of an ancient lava that had run iuto the sea, they surrounded them with their uets, and afterward discovered that they had been stunned by the mephitic vapors which at that time issued forcibly from underneath the ancient lava into the sea."

(To be continued.)

The Solar Eclipse of '93.

Professor J. M. Schaeberle, of the Lick Observatory, gave an interesting accounnt last week, before the Geographical Society of the Pacific, of his expedition to Chili two years ago, to observe the total eclipse of the sun. Of all the parties sent out to differeut parts of the world, this one obtained the best negatives. The story of the toilsome advance up the rugged Cordilleras, the difficulty of transporting the instruments as the men pauted in the rarified air, and the suffering in the icy blasts of the high altitudes, where the wind was almost a hurricane, were described by the lecturer with a force and vivid earnestness that held the large audience closely attentive till the end. The camera slides, illustrating the eclipse and many landscapes amoug the Audes, were well doue and gave great enjoyment. It is the professor's judgment that neither magnetism nor electric force has anything to do with the coronal display.

Books Received.

The Heating Power of Wyoming Coal and Oil, by E. E. Slosson: from the University of Wyoming.

The Discovery of Mineral Deposits in the Lake Superior Region, by H. V. Winchell.

The Twenty-third Annual Report of the State Geologist of Minnesota, by N. H. Winchell.

THE CALIFORNIA DEBRIS COMMISSION, having received applications to mine by the hydraulic process from A. Blair, in the American House Mine, near La Porte, Plumas Co., Cal., to impound tailings behind dams in the American House Ravine; from Jay E. Russell, in the Spring Tunnel and Spring Canyon Mines, near Mount Gregory, El Dorado Co., Cal., to impound tailings behind brush dams in Spring Canyon; from Porter Phillips, in the Mount Gregory Gold Mine, near Georgetown, El Dorado Co., Cal., to impound tailings behind brush and log dams in a ravine below the mine; from Wulff Bros., in the Deer Valley Mine, near Green Valley, El Dorado Co., Cal., to impound tailings in an old hydraulic pit; from John Enos, in the Strawberry Placer Mine, near Vallicita, Calaveras Co., Cal., to impound tailings behind rock dam in a gulch below the mine; from Geo. R. Evans et al., in the Red Hill and Telegraph Hill Mines, near Rancheria, Amador Co., Cal., to impound tailings behind log dam in Chili Gulch; and from Moy Jin Mun, in the Grizzly Hill Mine, near Volcano, Amador Co., Cal., to impound tailings behind brush dam in a ravine below the mine, gives notice that a meeting will be held at Room No. 92, Flood Building, San Francisco, Cal., on March 18th, 1895, at 1:30 P. M.

EDWARD S. COBB,
Mechanical Engineer and Expert.
Tests and Estimates for the improvement of Pumping, Power and Hydraulic Plants.
Will supervise the Construction, Shipment or Erection of Machinery. Will make Drawings, Estimates or Specifications.
Prices obtained for machinery of every description. Twenty year's experience.
123 California St., San Francisco, Cal.

MINE OWNERS!
An Electric Engineer with limited capital desires to correspond with mine owners who are now handicapped by the high cost of power, with a view to installing an electric power transmission plant on the property for an interest in the same. This applies to mines located within ten or twelve miles of available water power.
Address ELECTRIC ENGINEER, Care Mining and Scientific Press.

WANTED!
Mining superintendent to take charge of a silver mine in Mexico. Must be of good habits and thoroughly reliable in every respect, and have a practical knowledge of mining and milling silver ores and able to speak Spanish. No other need apply. Address BOX J, Mining and Scientific Press, 220 Market St., San Francisco, Cal.

PROSPECTING
Mechanics; Mechanical Drawing; Electricity; Architecture; Architectural Drawing and Designing; Masonry; Carpentry and Joinery; Ornamental and Structural Iron Work; Steam Engineering (Stationary, Locomotive or Marine); Railroad Engineering; Bridge Engineering; Municipal Engineering; Plumbing and Heating; Coal and Metal Mining, and the English Branches. Blowpiping outfit and mineral specimens *free* to students Send for Free Circulars, stating the subject you wish to study, to

TAUGHT BY MAIL THOROUGH PRACTICAL

THE JONES ROCK DRILL
IS THE
Only Successful Hand Power Drilling Machine Ever Invented.

It is strong, durable, reliable, simple, compact, light, easily handled and operated by one man, and will reduce the cost of rock drilling at least Fifty per cent.

Our handsomely illustrated pocket catalogue fully explains the features and workings of the drill. It should be in the hands of every mine owner, leaser, contractor and prospector in the West. *Sent free on application.*

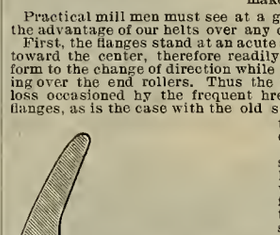
If you are interested in Rock Drilling Correspond with us.

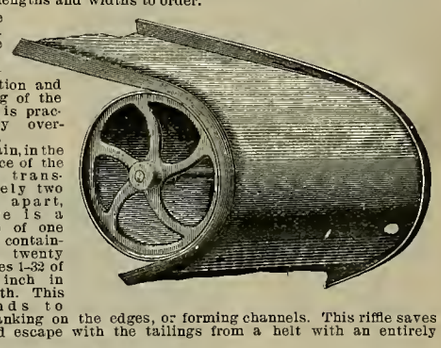
WE CAN SAVE YOU MONEY.

FRANK T. SUTHERLAND, M'g'r Pacific Coast Agency.
Office and Warerooms: 9 FREMONT St., San Francisco, Cal.
Or, Address the Company at its Denver Office.

Blasdel Improved Concentrating Belt.
We keep in stock belts suitable for the Frue, Triumph, Johnston and Tullock machines, and make all lengths and widths to order.

Practical mill men must see at a glance the advantage of our belts over any other. First, the flanges stand at an acute angle toward the center, therefore readily conform to the change of direction while passing over the end rollers. Thus the vexation and loss occasioned by the frequent breaking of the flanges, as is the case with the old style, is practically overcome.





Again, in the surface of the belt transversely two feet apart, there is a space of one inch, containing twenty riffles 1-32 of an inch in depth. This tends to equalize the pulp and prevents it from hanking on the edges, or forming channels. This riffle saves fine sulphurets and quicksilver that would escape with the tailings from a belt with an entirely smooth surface.

H. G. BLASDEL, JR., Manager,
419 California Street, Haywards Building.....San Francisco.

PLACER
Amalgamators, : Dredgers, : Shovels.
Complete "Lancaster" Cold Amalgamating, Concentrating and Hoisting plants furnished for treating large quantities of low grade placer ground at a small cost with minimum supply of water or compressed air. **Highest possible Gold yield insured.**
Outfits include "Lancaster" 1895 Land or River Dredges, Grapples, Scoops, Steam Shovels and Cableways of the most approved construction. Success guaranteed. Capacity, one hundred tons hourly and upward, if required. **Crushing, Pulverizing, Concentrating and other machinery also built.** Investigation solicited.
JAMES H. LANCASTER, Patentee, 39 Cortlandt St., NEW YORK.

Adamantine Shoes and Dies
—AND—
CHROME CAST STEEL
Cams, Tappets, Bosses, Roll Shells and Crusher Plates.

These castings are extensively used in all the mining States and Territories of North and South America. Guaranteed to prove better and cheaper than any others. Orders solicited subject to the above conditions. When ordering, send sketch with exact dimensions. Send for Illustrated Circular.
Manufactured by CHROME STEEL WORKS, Brooklyn, N. Y.
H. D. MORRIS & CO., Agent, 141 and 143 First Street, San Francisco.
Special attention given to the purchase of Mine and Mill Supplies

Stamp Cam.

En Passant.

A meeting has been called under the patronage of the Board of Trade, the Chamber of Commerce and the Mechanics' Institute, to consider the matter of local manufactures.

This movement proceeds from motives unquestionably good. One way to create home manufactures is to withdraw from the banks some of the money there lying idle and put it into shoe-making shops, implement factories, cloth-making and clothing-making establishments, etc., etc. The masses do not need to be educated so much as the capitalists. The masses are the buyers and they will buy where they can buy cheapest, and no system of "education" will make them do otherwise. Let capital do its part and the consuming masses will do theirs.

This regeneration of San Francisco is chiefly to be hoped for at the hands of her capitalists. Whatever has been accomplished in California in the past forty years has largely been absorbed by them. They are not, as capitalists go, a bad set of men, but they are deficient in just the sort of skill needed at this time. They are not, as a rule, men trained in business. Their wealth has very largely been acquired by inheritance, in speculation, by increase in the value of real property and by mining operations. So far as we know, there is not a good mechanic in the whole list of millionaires; and it is a very unfortunate fact. Just think what it would mean for California if her younger millionaires—leaving out of the question the older men, who are past an active life—had each some special business equipment! If Fred Sharon were a leather maker we should probably have the biggest and best tannery in the world. If young Phelan had been trained in the machine trade we might have an establishment which would build those forty-two locomotives for the S. P. If Charley Fair were an expert miner, it would set a thousand stamps to dropping. If Jimmy Flood were a shoemaker, the hide product of California would be consumed at home and "the masses" would walk in California-made shoes. Generally speaking, our great fortunes are employed in land speculations, in banking or in other ways which contribute little or nothing to the welfare of the city and State. The capitalists of San Francisco also need to be educated. And that the process is well in progress, and that it promises the best results, nobody can doubt who watches the movements of the times.

Obituary.

B. F. Bachman, an early pioneer of Los Gatos, who died last week, was one of the party that discovered the Yosemite valley in March, 1851.

Fred Oest, owner of the famous Oest mine at Silver City, died in this city last week. His mine has produced over $500,000 in gold, and at the World's Fair took first prize for gold specimens. At the time of his death Mr. Oest owned a half-interest in the mine.

John J. Devine, one of the best-known mining men in southern Arizona, was found dead in bed at a hotel in Florence, Arizona, on the 1st. He made and lost several fortunes in the mining business in the Territory, and at the time of his death was superintendent of a company which controls rich gold properties.

K. A. Denison, a prominent assayer and mining man, of Leadville, Colo., died February 26th from accidental poisoning. While taking lunch in his office he filled a tumbler with water, thinking it was clean. It contained four or five drops of cyanide of potassium, and he died in an hour. Mr. Denison was a popular man, and was to have been married in a month. His mother resides in Geneseo, N. Y.

A Sweeping Decision.

An absolute removal to all bars to the use of the carbon telephone transmitter; the destruction of exclusive rights to manufacture and sell the incandescent light; the denial of right, alleged under an Edison patent, to impose a royalty upon every street railroad or any other enterprise using electricity for power or light; the collapse of claims for royalty for the usé of machinery in the rubber industry and probably in numerous other industries; the probable beginning of suits for the recovery of royalties paid under patents now decided to have expired—these are some of the results of the decision handed down by Justice Harlan last Monday in the Bate-Sulzberger case.

The Bate-Sulzberger case was made up in New York by counsel representing the American Bell Telephone, the General Electric and the Western Union Telegraph Companies on one side and the Westinghouse Company on the other.

The Supreme Court affirms all that was claimed by Shultzberger and settles forever what constitutes the life of an American patent. As to its effect, it first of all removes completely all proprietary rights to the patents covering the carbon or battery telephone transmitter. The Bell Company claimed this enunciator under the Berliner patent, which was decided against the company by Judge Carpenter in the lower United States Court in Boston several months ago. The Supreme Court decision and that of Judge Carpenter makes it possible for any one to use the carbon transmitter. The Bell Company still holds numerous small devices, but its fundamental grip is gone and now the way is clear for rivals.

Another great electrical patent which is destroyed is that issued to Edison in 1887, known as No. 369,280, covering a dynamo with translating devices in a multiple arc. Little has been said about it in the newspapers. It was a patent broad enough to cover every device for transforming electrical energy into mechanical energy. The company which holds it began suits under it in the winter of 1893-4 to enforce payment of royalties. The institution of the Bate-Sulzberger case caused those suits to be continued.

There are other minor patents involved. The capital which is interested runs possibly to $300,000,000. The decision affects not only the electrical industries, but throughout mechanical industries the effects of the decision are felt. The rubber industry is heavily involved and a number of others.

Recent Additions to the Collection of the State Mining Bureau.

Dumortierite from Ogilby, Cal.; selenite from Utah; aragonite from Arizona; arfvedsonite in microcline from Colorado; white and yellow topaz in matrix from Utah; albite and microcline from Amelia Courthouse, Virginia; celestite, fluorite and siderite from England; cerussite from Broken Hill, Australia, and from Bohemia; corundum, rutile and kyanite from North Carolina; epsomite from the New Almadeu mine, C. C. Derby; beryl from Siberia, J. Z. Davis; fluorite from New York, J. Z. Davis; pink crystals of apatite, J. Z. Davis; polished specimens of travertine, Verde antique and other marbles, A. L. Seager; gold quartz with telluride of gold from Siskiyou Co., Cal., B. S. Thomas; fossil fish from the foundation of the Courthouse at Los Angeles, T. Shooter; a number of new fossils from the Los Angeles and Puente oil districts and also numerous specimens of gold quartz, silver and other ores, rocks and minerals, etc. Henry S. Durden, Sec'y.

Colorado Mining Stocks.

Colorado Springs, Colo., March 2, 1895.

To the Editor:—Universal indifference towards every class of mining-stock speculation prevails with little evidence of any change. What little activity remains emanates either from some contemplated reorganization or various schemes to secure controls, etc., and possible professional speculation. There is no investment interests apparent.

It may appear ridiculous to pose as a bear at this time, although general opinion is that everything is cheap; but with very few exceptions, everything will probably be cheaper. One of the chief reasons for this is that mining-stock traders invariably represent the high-pressure class of business men, carrying more than their circumstances warrant and always being forced to realize at short notice, thereby creating many advantageous opportunities to invest.

If the Denver and local exchanges would co-operate and take pattern after the New York Stock Exchange and other institutions of the same class and insist that the stock books of the listed companies should be subject to the inspection of the stockholders at reasonable times, there would be more confidence, and ordinary speculators would receive at least a portion of the consideration they are unquestionably entitled to. Besides, there would be less likelihood of over-issues, exorbitant salaries and various other dishonest complications that are becoming altogether too frequent. A shareholder in a stock company is a partner in the concern, and there is no other way of defining his position.

I have in mind several well-known mining companies, the value of whose stock has recently depreciated very much. The books of these organizations are peculiarly difficult to inspect and reliable information an impossibility, and those supposed to have the reputation of conscientiously directing their affairs are particularly sensitive to comment of any nature whatever. This in itself shows that there is material for reform. If a few of the individuals connected with certain companies which have accomplished a great deal of questionable manipulation are to govern the entire mining stock market, the sooner the business is abandoned by those who desire to retain a respectable reputation the better.

There are undoubtedly many attractive purchases in the Cripple Creeks, but what recommends some of the silver propositions to the investor, few attempt to explain. One pleasing feature is that more attention is being given to legitimate mining than ever before, and the good results are daily increasing. Very respectfully, F. H. Pettingell.

The S. P. Co. has placed an order for forty-two locomotives with Eastern firms. The fact emphasizes the industrial condition of the city and State. This half-million-dollar-order would be a fine thing for a California establishment.

Scientific Progress.

The Origin of Kerosene Oil.

Mr. John W. Rock, writing iu the *Australian Mining Standard*, says: The eminent French microscopists, MM. Bertraud and Renault, have by their researches settled the vexed question of the origiu of keroseue shale.

The writer is very sanguine and believes that these great Frenchmen have disposed of all the previous theories claimiug to establish for the prime cause, all kinds of organisms "ranging from forest tree to jelly fish."

It is allowed, however, that Professor David was right in the theory he set up, because it is in line with the deductions of Messrs. Bertraud and Renault.

Thc co-relation of the microscopic observations, according to Mr. Rock, lead to the conclusion that at the close of the carbouiferous period there existed in the now known oil regions "a series of shallow lakes fed by streams which carried sediment iu their waters and deposited it, in greater or less measure, on the bottom of the pools, mingled with innumerable leaves of the *gloss-opteris* (tree fern), which floated down with the current.

But the remarkable feature of this discovery of the origin of kerosene, traces it to the fecundating polleu of the prevailing plant family *Filices*, or feru family, that arc known not to shed their pollen from stamens like the phanerogamous order of plants but like true cryptogamia or non-flowering plants, for in the past, even much more so than now, they cast off their pollen as *spores* out of their spore-cases, called *sporangia*, and as the spores of the fern are not seeds, but fecundating germs, a fern plant is the second growth from the spore; therefore nature has made thc fern to produce in prodigious quantities the spores that seldom germinate, because, under the most favorable conditions of climate, few fiud a suitable matrix favorable to their biogenesis. We need not wonder then when we are told that this family of plants sometimes cast off spores sufficient to cover the floor of a forest to the depth of au inch in one year.

Mr. Rock next proceeds to say: "All around were forests of *coidaites*, from which, iu common with large areas of country, a ceaseless rain of pollen fell upon the surface of the lakes, each particle becoming macerated aud finally mingling with the mud at the bottom, forming the bitumiuous shales which exist in varying thickness below and above the kerosene bands."

He finds the coincident productions aud couditions necessary for nature to furnish her supply of kerosene to be:

1st. The presence of shallow lakes fed by the waters of numerous streams that traverse the neighboring forests.

2d. A hot damp climate, and large forests of tree ferus that throw off immense showers of pollen or sporangia.

3d. The waters of the stream must contain a peculiar vegetable matter called ulmic acid.

4th. The surface of the lakes must be covered with a miuute genus of algæ of rapid growth and ephemeral existence.

The writer further proceeds: "At the same time the waters became impreguated with a peculiar brownish vegetable matter, kuown as ulmic acid, such as is to-day found in the rivers Amazon and Orinoco in South America.

"Still the pollen from the forests fell upon the surface of the lakes and became water-logged, and sank to the bottom, mingling with the brown material that yielded the ulmic acid.

"But now a new phenomenon occurred. All over the surface there appeared a growth of minute plants of the genus of algæ, each consisting of a gelatinous, sac-like plant, floating free and containing many hundred cells. Each as it disappeared below the surface was replaced by another, to follow in its turn and descend slowly and gently to the bed of the lake, where rank on rank was deposited until, in some cases, 40,000 layers were piled up in a semi-fluid mass about twelve feet in thickness."

The mass then evidently dried up and the thickness mentioned above would shrink to about four feet six inches, forming one of our most valuable kerosene deposits.

Production of Ozone.

According to foreign chemical journals, the most recent method of producing ozone is that of Lieut. Poulsen, a Danish officer, aud is based upon the oxidatiou of phosphorus in a special apparatus. A wide-neck glass jar is closed with a fiuely perforated porcelaiu plate, and two iuches below this there is a similar plate inside the jar. Through the center of each passes a rod, which is curved upward at the lower end and terminates in a small cup for holdiug a piece of phosphorus. The jar contains sufficient acidulated water to submerge the phosphorus when the apparatus is not in uso, and, when ozone is required, a small quantity of potassium permanganate is added to this, and the phosphorus raised by means of the glass rod above the surface of the liquid. Phosphorus acid is formed by contact of the phosphorus with the air, and converted into phosphoric acid by the action of the permauganate, while ozone is produced simultaneously and escapes through the perforations in the porcelain plates.

Paper as an Insulator.

For mauy purposes paper is an excellent insulation, and has come into use in telephone and other cables. Such an insulation has beeu tried under water. One such cable is now at the bottom of the Hudson river at New York, in the track of all domestic and sea-bound traffic. The cable is lead-covered and otherwise protected, but depends for its insulation, electrically, on thin spirals of paper around each stranded interior wire. The laying of such a cable iu such a place might, a few years ago, have beeu considered little short of suicidal, but experience has demonstrated the practicability of the scheme. A 100-pair, paper-insulated, lead-covered cable can be bought for fifty cents a foot, while the rubber-insulated cable would probably cost not less than $3 per foot.

RECENT experiments show that glass is more porous than has been before thought. A vessel was partitioned into two parts by a light of glass, and on one side the vessel was filled with sodium amalgam and on the other with pure mercury. The whole was heated to a temperature of 200°, where glass begins to be very conductive. The two sides were then connected with the positive and negative wires of a battery and a current of electricity passed through for about thirty hours. At the end of this time it was found that quite considerable sodium had found its way through the glass into the mercury on the other side. Neither the original weight of the glass nor its transparency was in auy way changed.

THE Governmeut is testing a new plan for signaling at sea, which has already yielded remarkable results. It consists merely of an ordinary gong fastenod to the bow of the ship below the water line. This acts as a transmitter, and the receivers are gongs of exactly similar tone and rate of vibration, oue on each side of the ship below the water line. The receiving gong will take up and produce the sound of the sending goug from a long distance. Signals already have been clearly transmitted ten miles.

M. DEBOIS, of Reuleaux, France, has patented a new mixture, which, when burned, will withstand the highest temperatures. The mixture is composed of quartz or flint and sulphate of borium. The proportions are varied according to the needed resistance of the material, iu some cases, ground. Pudding stone is also added to the "mix." The moss, when moistened, will take any shape like ordinary fire clay, and is dried and burned in the same manner.

LORD KELVIN says that the earth might be white hot two thousand feet below the surface, or as cold as ice fifty feet below, without changing our present climate. He attributes the intensely hot climate of an earlier age to greater heat of the sun.

Mechanical Progress.

A New Electric Locomotive.

A uuique electric locomotive is building at Boston, Mass. The distinctive feature of the invention is the substitution of a piston and cylinder instead of the usual rotary power. The cylinder is much longer than for steam purposes, and has in its interior a series of magnets. The piston passes entirely through the cylinder, with crossheads at either end. On the piston within the cylinder is a series of armatures of peculiar construction.

On the axle of the driving wheels are commutators, whose funetion is to apply and cut off the electric current, just as the eccentrics control the steam of the steam engine. The principle of the machine, which is of 8-H. P., is the admission of the current to the magnets in the cylinder, which are in advance of the piston rod, and hy their action on the armatures the piston rod is moved forward. As the stroke is ended, the current is shut off from the magnet first charged and applied to those at the rear of the piston, giving it a reverse motiou, thus maintaining a strong, regular motiou. There is absolutely no back pressure from the electric current, while iu a rotary motor this is estimated at tweuty per cent of the force applied.

It is practicable to run the machine at 200 revolutions of the axle per minute, and with a driving wheel eight and one-half feet in diameter, and the crank pin three feet from the center, there would be a six-foot stroke under a full head of power. The machine is adapted to receive the electric current either by a trolley wire, a third rail in the track, or from a storage battery.

How To Make an Engineer.

Speaking at a meeting of the Leeds Association of Engineers, on the 1st of Decemher, Mr. W. Clayton, M. Iust. C. E., who presided, said that we were told we were not to compete with foreign rivals, because Continental people had superior technical education. It was uothing of the kind. Continental nations were able to compete with us because they could supply at lower prices, and that, in turn, was because men worked longer hours for less money. Technical education was a good servant, but a had master, and conducted on the liues at present pursued in this country, would lead to nothing hut disaster. It was no use sending a lad for three years to a technical school, and then at nineteen or twenty years of age giving him a few months' experience in a workshop. To make a good engineer, the good old plan of apprenticeship must be adopted. Let a boy get used to his work, and then let him learn, what he could never do at a college, business habits. This was the only way to make an engineer, and no other way would be successful.—Scientific American.

In the great majority of cases it pays to do things the best you are capahle of, regardless of the expense of time and material required. The mechanic often meets with conditions under which he is tempted to "rush things" to a degree which forbids anything hut the shabbiest work. It may seem at the time that the circumstances justify it, but he generally finds afterwards, if he has yielded to the temptation, that palpahle loss resulted from his haste. The circumstances are rare which really recommend makeshift work. The mere fact that a man has underestimated the price of a piece of work, or the time in which it could be finished, is of itself no reason for sboddy execution —in nine cases out of ten.

Those who have traveled much by rail are more or less acquainted with the hot box. A hot box, as it is commonly called, really means a hot journal bearing on a hot journal, or both. It ariscs sometimes from the use of poor material in the bearing, sometimes on account of imperfect casting and sometimes from too great weight upon the bearing, producing friction and heat. There are now fewer hot boxes than formerly. Some of the heaviest cars are now carried upon six-wheeled trucks, thus distrihuting the weight of each end of the car upon six journal bearings instead of four, and reducing the danger of excessive friction. Better materials are used, and the workmanship upon them is better; weights to be carried are calculated more nicely and greater care is exercised in operation, so that the hot box is not what it once was. A man thoroughly familiar with railroading, who made, uot long ago, a trip of 10,000 miles, which included points as far apart as the City of Mexico, San Francisco and Chicago, said he did not encounter a hot box until he was within twenty miles of New York on his return.

Some engineers do not clearly understand why an engine is so wasteful of the heat units derived from coal comhustion. We are told by the scientists that only about six or eight per cent of the total heat value of coal is utilized in the engine by heating transformed into power. In tracing up this loss the engineer is told that it requires 1202° of heat or heat units (not degrees of temperature) to change one pound of water into steam. Duriug the absorption of this amount of heat the temperature of the water remains at 212°. This immense amount of steam is rendered latent, and does not sensibly affect the thermometer. The cause of the loss in the steam engine is then, that the 990° absorbed by water in being transformed into steam (212° are apparent upon a thermometer, which added to 990° make up the 1202° mentioned above) go into the engine unindicated by the thermometer and they leave in the same manner, and go to waste. This, then, is the main cause of the heat loss in steam engines.

In handling heavy machinery it is necessary to take every possible advantage. If three sticks of timher can he procured and set up at an angle, with the upper ends lashed tightly together, a support is thus formed for the hoisting tackle, with which almost any machine can he quickly unloaded from wagou or railroad car. Sometimes two sticks of timber are available when three cannot be had. The two may then be lashed together and erected, heing held in place hy two guy ropes. Sometimes even two sticks cannot be had and the work must he done with one. When reduced to the use of a single mast at least three, and better four, guy ropes are necessary. The guys may he quickly tightened by the use of a small rope tackle, and when once in place, machines can be easily handled by a heavy tackle suspended from the top of the mast.

The journal *La Metallurgie* describes a steam hammer patented during the past year, in which the hammer proper constitutes an air cylinder. In this cylinder moves a piston actuated by a crank, connecting rod and lever from the driving shaft of the machine; and the cylinder is pierced by holes, connected interiorly one with another and placed equidistant from its ends, allowing a free entrance and exit of air. By virtue of the movements of the piston and of the cylinder or hammer, which at certain instants are opposed, the holes are closed hy the piston and the air remaining below or above serves to give elasticity to the movements of the hammer.

When large boxes are filled with habbitt metal the lining is frequently found loose. This is caused by contraction of the metal during solidification. It is necessary to tighten such a lining hy hammering the entire surface of the soft metal. A hall peue hammer should he used, and the entire surface of the babbitt hammered over, after which the box should be bored out in the lathe to the required size.

Commodore Melville, U. S. N., expresses the opinion that not only speed but maximum economy in fuel will be attained through the use of the triple screw in steamships, each acting independently of the others, the center one alone being used for slow cruising. Other expert naval engineers concur in this opinion.

The trade winds are the prime motors of ocean currents. They cause a surface drift of no great velocity over vast areas of water in the same general direction as that in which they blow. These drifts, after meeting and combining their forces, eventually impinge on the land. They are diverted and concentrated and increased in speed. They either pour through passages between islauds, as in the Caribbean sea, or are pressed up by the land and escape hy the only outlet possible, as, for example, the Strait of Florida, and form a great ocean current like the Gulf Steram.

Engineers have figured out that Niagara would continue to pour for 100 years if the sources of supply of the Great Lakes should be dried up. Other engineers calculate that when the Chicago canal is finished and in operation, the water level in the lakes will be lowered nine inches—perhaps much more.

MacArthur-Forrest Process.
CAPITAL, - - - £110,000 STERLING.

To MINE OWNERS and others having Refractory Gold and Silver Ores hitherto untreatable at a profit, the MACARTHUR-FORREST (Patent) Process of Gold and Silver Extraction offers a solution of the difficulty.

Advisory Board in the United States: Thomas W. Goad, Manager; Hugh Butler, Attorney; John F. Bell; P. George Gow.

California and Nevada Agency and Experimental Plant, 23 Stevenson Street, San Francisco, Cal. P. G. Gow, Sole Agent.

OFFICE: McPHEE BUILDING, DENVER, COLORADO.

RUPTURE!

It has been considered by the medical profession that hernia—commonly called rupture—was incurable, except by surgical operation, which is both dangerous to life and very rarely ever successful. But DR. J. C. ANTHONY, of 86 and 87 CHRONICLE BUILDING, has opened a new field for research, and for the past year has been making some remarkable cures. He causes the patient no pain, and those living near enough do not lose any time only while in his office once or twice weekly. He guarantees every case he treats, and does not ask a man for a dollar unless he cures him, so there can be no chance of any one being cheated. The doctor is a graduate of Bellevue Hospital Medical College, of New York City.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

MINING ITEMS.

GOVER.—*Record:* Another change has taken place in the affairs of this mine. J. M. McDonald, at whose expense the mine has been kept free from water for the past five months, has withdrawn from the undertaking, and notified all parties concerned that he will no longer be responsible. An agreement has been entered into between the company and C. E. Purington, by the terms of which the latter is to take immediate charge of the Gover property, and, it is said, proceed to work it. He wishes to make arrangements with the creditors to enable him to work the property, and is expected to be up here shortly for that purpose.

ZEILA.—All the heavy work in the repairing of the mill is through with except placing the mortars and stamps in position. Two of the mortars were on the ground the first of the week, and another was expected Tuesday. The concentrator floor is being renewed. It is expected that another month will find the entire works—mill, mine and reduction plant—ready for entering upon another protracted era of gold production.

ZEILA CHLORINATION WORKS. — After the longest life probably on record for such works, the furnaces of the Zeila chlorination works are being rebuilt. The furnaces lasted fourteen years—in fact, ever since the resumption of work at the mine by the present company. For five years and fifteen days from the commencement of operations the fires were never extinguished, and at the expiration of this protracted period of service the floors only had to be renewed—not that they were actually worn out, but had become so uneven as to give the employes considerable trouble in scraping out the sulphurets. After repairs the works ran until the present time. The furnaces, notwithstanding the unparalleled record of longevity, were not completely worn out. It was not absolutely necessary to rebuild them. They would doubtless have done good service for years yet, with slight repairing. But inasmuch as a cessation for over a month was inevitable, and as the capacity of the old works was unequal to keeping pace with the product of the mine, it was deemed advisable to rebuild on a larger scale. The old furnaces were of three tons capacity, and somewhat overworked at that. The new furnaces will be of from 3½ to 4 tons capacity. With a practically new mill, it is expected that considerable more rock will be crushed per day by the forty stamps than of late years, and even with the increased size of the chlorination works, it is expected that enough sulphurets will be turned out to keep them steadily running to their fullest capacity. The extended life of the Zeila reduction plant is deserving of special note. Ex-State Mineralogist Irelan is reported to have stated that he believed the experience of the Zeila was without a parallel in any mining region on the globe. Mr. Detert, when the old works were first started, said he would make them last without repairs for five years, and this limit was exceeded by fifteen days. But a life of fourteen years without complete renewal would have been laughed at as utterly unattainable.

The five-stamp mill of the Smith Bros., on the Clough claim, came to a stoppage for a week owing to a break-down, which necessitated sending to San Francisco to replace the broken machinery. The mill is again running. No cleanup has yet been made.

Twenty stamps of the Keystone mine are running.

Another strike of rich ore is reported in the Mayflower mine. Rock heavily charged with free gold has been lately taken out.

Butte.

LOSS OF GOLD.—The loss of gold in quartz and other forms of mining is much greater than most people imagine. T. W. Reesce says that sixteen years ago at Cherokee an undercurrent was placed at the end of the tail race a mile and a quarter below the head of the flume. Twenty-four of these undercurrents were placed along the upper part of the big flume, and these were supposed to save every pennyweight of ore from the mine. This last undercurrent was put in simply as an experiment, but in six months when it was cleaned up, between six and seven hundred dollars were obtained.

Calaveras.

HAS NOT CLOSED DOWN.—*Echo:* The *Prospect* of last week had some grievous errors in regard to the Central Hill mine at Douglas Flat. That paper stated that the Debris Commissioners had ordered that operations be suspended at the mine. On the contrary, Messrs. Kidder and Huer, the Commissioners who inspected the property a couple of weeks ago, authorized the owners to begin hydraulicking when a restraining dam is constructed. The site selected for the dam is about 200 yards from the mouth of the tunnel. The dam will be ten feet high, but, of course, it will be added to from time to time as it fills up. It will be finished in a couple of weeks, when the Commissioners will again inspect it and determine whether it was built according to specifications. Meantime, the company is sluicing as usual.

A HYDRAULIC MINE CLOSED.—*Prospect:* Murphys seems to be out of luck, and now has received another black eye by the closing down of the Bisbee, McCormick & Thomas hydraulic mine at Central Hill. This mine, after the expenditure of thousands of dollars in running a tunnel to tap the mine, is forced to suspend operations just as the owners were about to realize some return for their expenditure. Though the debris from this mine is carried over land, and the right of way owned by the owners of the mine for many miles, before it reaches the upper course of the Stanislaus, which is not a navigable stream, all operations must be stopped for want of restraining dams. Hon. John F. Kidder and Major W. H. Huer, Debris Commissioners, went up Friday, and after visiting the ground ordered operations to cease. It is thought that dams can be built at small expense that will enable the mine to resume. Meanwhile the season for hydraulicking passes away and the owners must go down in their pockets for coin.

Del Norte.

THE USUAL CLAIM.—*Record:* We learn there are parties from Portland here who have a black-sand mining machine of their invention, which will be put up and thoroughly tested on the beach below town. The owners of this machine, like those in the past who have been here with devices of the same kind, claim that it will save all the gold in the sand without a doubt.

Nevada.

THE NORTH BLOOMFIELD MINE.—The ditch of the North Bloomfield gravel mine has been closed for over two months, with small prospects of getting it open again before early summer, owing to landslides and destruction of flumes by heavy snows. The company has had some "way water" for a short time, but a large landslide above Relief Hill has cut that off and effectually closed the ditch for some time to come. The company, it is said, will make no effort to open the ditch until the snow melts.

THE HARMONY MINES.—*Herald:* The Harmony mines have resumed operations. The mines have been suspended for several weeks, but will probably not be troubled any more this season.

ELECTRIC MINE.—The Electric mine, which has had some trouble with water the past winter, is gaining on this difficulty at present, says the *Telegraph*. There are still two levels submerged, but by freeing one of the levels recently an additional force of men has gone to work. Supt. Coffin states that there are now about thirty miners engaged at the Electric.

THE YUBA.—It is rumored that the Yuba mine, Maybert, will begin operations again soon. The Yuba is a good property, and if properly developed would make a paying mine again.

INCORPORATION ARTICLES FILED.—*Transcript:* Articles of incorporation of the Red Dog Mining Company were filed in the county clerk's office. Principal place of business, Nevada City. The object of the company is to purchase, locate, acquire and operate mining ground, and to lease, purchase and acquire water rights and ditches. Amount of capital stock, $30,000, at $1 a share. The following are the directors: John Spaulding, W. F. Englebright, J. S. Goodwin, Martin Lawrence, R. E. Linder and F. Goding, all of whom subscribe for 5000 shares each.

MINE BONDED.—*Telegraph:* Timothy Hurley and others have bonded the General Grant mine. The mine is located about half a mile southwest of Forest Springs and is owned by Martin Ford, John Tierney and Alfred Perrin. There are two tunnels on the mine; one of them is about 1000 feet in length. The ledge is fully eight inches in thickness and the ore yields $65 per ton. The last work done on this mine was in 1872, and during the active operation of the mine some $50,000 were extracted from the ledge. At a very early day suitable machinery will be placed on the claim.

RICH ORE.—At the Champion mine the rock is of extra good quality; many beautiful and valuable specimens are daily extracted. The mine is running at full blast, the entire thirty stamps being constantly in use.

GENERAL NOTES.—The Culverson mine at Graniteville, which has been shut down on account of the water ditch being blocked, has started up again.

The National resumes operation this week under the supervision of D. T. Powers. It will take about a month to pump the water out, after which the full crew will be put to work again.

The ten-stamp mill at the Erie mine will soon be remodeled and started crushing rock in about a month. The tunnel will tap the ledge at a depth of about 700 feet.

Plumas.

MINING ITEMS. — *National-Bulletin:* The Lucky S. mine will start work as soon as the weather will permit.

Joseph Gruss, superintendent of the Genessee mine, will shortly resume operations.

At Gopher Hill the Quincy Mining and Water Co. is ready for a big season's work. At the head of their extensive water system there is now probably fifteen feet of solid snow, capable of maintaining an effective water supply till late in the summer. The company will operate on a large scale.

Pitner Trayner, the superintendent of the Northern Placer, will return from below in a few days. As the snow is beginning to melt in the vicinity of the mine, the washing of the gravel will soon begin. The mine is fully equipped for active work.

At Mills' shaft the rain last week and the rapidly melting snows produced such a volume of water at the mine as to cause a suspension of work until there shall be less to contend with. It is probable that work will be resumed underground in a short time.

Much activity is expected at Granite basin during the coming summer, though operations cannot be resumed at a date as early as usual, on account of the heavy snowfall in that section during the past winter. Last fall that mining camp was visited by numerous mining men seeking investment or hunting for prospects to develop. Several locations and investments were made, and doubtless more will follow during the coming season. That country has numerous small and rich veins of quartz.

Placer.

THE GOLD RING.—*Sentinel:* The Gold Ring gravel drift mine at Green valley, three miles south of Dutch Flat, is at present doing better than at any time in its history. During the past month some fine nuggets, ranging from $4 to $16, have been found. Supt. Ames employs twenty-four men. There are a number of promising claims in Green valley.

THE BLACK HAWK.—The Black Hawk mine at Forest Hill, formerly the Kirk property, was bonded this week to J. P. Mallette, of Chicago, for $40,000. He is the recent purchaser of the Zantgraf mine for $150,000.

OPHIR DISTRICT.—The Boulder and Hathaway mines at Ophir bid fair to be dividend-paying mines. The Hathaway is owned by Colgate, the soap king. At the Boulder fourteen men are engaged in stoping, breasting out, and getting the mine in shape for working. A reservoir has been cut out off from the main drift, into which all the water (mostly surface) will be run.

THE GOLD BLOSSOM.—The Gold Blossom is at present at a standstill, until larger machinery is put in. The company now running it under bond claim that it will pay, and pay big, with larger machinery capacity. The ore is being worked by the Hopper drying process, and it is claimed that $8 rock will produce $30, but it takes too long to work a ton.

THE MARGUERITE.—At the Marguerite a six-horse power engine and pump are being erected, and in another week the working force will be increased to fifteen men.

Riverside.

PROGRESS AT PERRIS.—A year ago there were but two mills at work in the Perris district—one a diminutive five-stamp prospector's mill and the other an antiquated rotary, which for several years had been worked on the Good Hope. There was also a five-stamp mill lying idle on the Menifee mine at Menifee. Since then a twenty-stamp mill has been erected on the Good Hope, a ten-stamp on the Santa Rosa, a five-stamp on the Santa Fe and a five-stamp on the Alice mine. Besides these, mills have been put up on the Infidel and Briggs mines, and all are bringing in fair returns to their owners.

San Bernardino.

RICH GOLD STRIKE.—McHanly Bros. report locating a ledge in the Pinon district, sixty miles east of Banning, on the borders of Riverside and San Bernardino counties, which gave $915 gold from three tons worked at Tingman's mill.

San Diego.

Thomas Kaine has sold to Amanda J. Page for $400 the Bonanza quartz mine and the Golden Deposit placer claim in Mesquite mining district.

Sierra.

MINING ACTIVITY.—*Messenger:* Five stamps are running at the Wm. Tell mill, and the quartz is said to pay very well. Forty stamps are running at the Bonanza mine and fifty-five men are working there, many of whom are from Downieville. The Sierra Buttes miners have been clearing the company's large flume of snow to bring in water, and are now once more working in the mine. It is reported on good authority that the Bigelow ledge will be reopened this coming summer and operated on an extensive scale. Many men are unemployed, but will soon be busy again.

Siskiyou.

MINING NOTES.—A company from Oregon, Messrs. Fulton, Espy, Denio and Hunter, have bought from Quinue & Simmons forty acres of mining ground on Rocky Gulch, to be worked by hydraulic process. A 200-horse power pump is to be placed at Shasta river, and operated by water power in extending the electric light plant ditch 500 feet farther down the river for securing sufficient pressure upon a large wheel. The water from the river is to be forced through 1100 feet of pipe, to an elevation 400 feet above the river, then carried through a flume three-quarters of a mile to the diggings. The water will flow down into Yreka creek, and thence back to Shasta river again, nearly two miles above where it is taken out, and if extended to Greenhorn, across Yreka flats, would run back into the river just the same by reaching Yreka creek, of which Greenhorn is a tributary. The cost will approximate $25,000. It will take about $15,000 more to place it in working order, by using a wheel, pump, building flume, etc. It is expected everything will be in readiness to commence taking out gold in about ninety days. The claim is two miles north of Yreka.

The hydraulic mines at Oro Fino are being worked; there is an abundance of water to keep the giants well supplied for continuous piping. The water supply, owing to the great quantity of snow on the mountains, will last until very late in the season, giving assurance of the greatest yield of gold ever realized in that rich mining camp.

At Little Humbug and Horse Creek, on the Klamath river, above and below Oak Bar, the miners are at work in their placer claims.

The miners at Indian Creek are commencing to get ready for mining, now that the snow is melting rapidly to furnish plenty of water.

The Red Hill hydraulic mine, in Black Bear district, Salmon river, is being worked on an extensive scale. A large yield of gold is anticipated this season.

The mining companies at Cottonwood are making preparations for extensive operations. Jillson & Co. and the Black Jack Co. will start their new quartz mills in a few days, to crush the blue gravel cement from their claims, which prospect very rich.

Tuolumne.

THE LADY WASHINGTON MINE.—This mine adjoins the Eureka and Dead Horse mines to the north, and is located on the west side of the mountain slope, that rises from the north fork of the Tuolumne river 2500 feet to apex. It is further situated in the Summersville mining district. A very rich strike of unusual importance has just taken place in the above mine which demands more than a passing or casual notice from the fact that this particular vein has heretofore escaped the observation of the past owners of the mine. The Messrs. Rule and Doe have, during the last few months, spent considerable money prospecting and developing the property. Their work was confined to the east vein principally but about three weeks ago. The Messrs. Rule made a careful examination of the surface surroundings to try and find another vein that was known to exist, and known as the west vein, being on the true footwall, and is granite. The hanging is slate, hence a contact vein. Having thoroughly explored the mountain side, they were rewarded by finding some croppings and a sign of a footwall. Determined to enter a tunnel at that site, which is 200 feet below any of the works on the east vein, they quickly struck quartz. The tunnel is now entered 18 feet, disclosing a 12-foot solid lode which shows free gold disseminated through the whole mass from wall to wall. The gold is fine, but in such quantities that is easily visible to the naked eye. This rock will mill, on a most conservative estimate, $100 per ton. They have already passed through several feet of this rich ore body. The rock in the breast is of the same bonanza character. To what distance this shoot will run is only a matter of conjecture. From the floor of this tunnel to apex of lode gives 1100 feet of backs, or from their lowest tunnel level will give 2300 feet. Hence it will be seen that this rich find is of the greatest importance. This development actually makes a new mine of the Lady Washington. This discovery has infused untold encouragement to all the mines in the vicinity. Prospecting in every direction is the result of the impetus given by this new find. I am pleased to be able to state that the Seminole group of mines are looking exceedingly well. Their present mill of ten stamps is pounding away day and night on good ore. This company proposes, in the near future, to erect another mill of twenty or more stamps at their low tunnel level on the north fork of the Tuolumne river, which will be a crosscut to open up and develop the whole group at a great depth. This step is a wise one, as it will enable the management to work this ore most economically. This group of mines lie to the southwest of the Lady Washington, Eureka and Dead Horse veins, but not on the same lode, but may be found of equal value when developed. From the present outlook that fact seems to be assured.

ALASKA.

JUNEAU TO FORTY MILE.—There are sixteen to eighteen saloons at Juneau and about the same number at Douglas City, one mile away, across the channel. There are about 1500 people at Juneau and about 750 at Douglas, and 400 or 500 men out of employment. After reaching Juneau it requires between $200 and $300 to get to Forty Mile, which is about 800 miles northeast, with bad mountain roads, rapid streams and portages to overcome on the way. The placer mines are about as far from Juneau as Billings, Montana, is from Seattle. Town lots at Juneau and Douglas are held at high figures.

ARIZONA.

ANOTHER MINING DEAL.—*Herald:* One of the most considerable mining deals ever consummated in this place was brought to a close yesterday when Major W. A. Rowe sold to H. J. Sisty and W. A. Clark, of Colorado Springs, the celebrated Shelton group of gold mines situated on Lynx creek, fifteen miles from Prescott. The purchasers are well known in mining circles, having, not a great while ago, sold the King Darrow mine in Cripple Creek district. They propose to commence work on an extensive scale, and will erect a new twenty-stamp mill on the Shelton properties. The group consists of thirteen claims, five of which are the personal property of Major Rowe, who regards Lynx creek as the coming gold-producing section of Arizona. A year ago when he commenced work there he says not a blast could be heard going off. Now one mill is running steadily, another is about to start up, and the twenty-stamp mill for the Shelton group will make the third. While the purchase price is not given, the reporter was assured that "it is one of the biggest deals for years." An excursion party of Colorado capitalists, who are also in the deal, will soon visit this section and the mines.

THE MAMMOTH.—The Mammoth mill is in constant operation. About sixty-five men are employed. Fifty stamps are crushing ore from the Collins group.

THE DEL PASCO.—*Courier:* In the Del Pasco mine, at a depth of 400 feet in the 700-foot crosscut tunnel, four inches of solid metal has been struck, in contact between porphyry and slate. There is two feet of ledge matter in the drift to the north. The mine is now worked by J. A. York and Wm. Vanderhilt. It is a famous property, which has produced $2,000,000 in gold. Lester Jackson at one time leased it to Gohin & Robbins, and they took from it in six months $40,000.

BRITISH COLUMBIA.

CONCENTRATOR WORKING.—The concentrator of the Slocan Milling Company below Three Forks is running. In the experimental run 500 tons of Alamo ore was put through, yielding 200 tons of concentrates, averaging 160 ounces silver and 72 per cent lead. In less than a year, since Captain N. W. Moore, who is at the head of all the Duluth syndicates operating here, they have acquired title to over $500,000 worth of mining property, consisting in part of the Ivanhoe and Elgin, the Idaho mines (of which George W. Hughes owns one-third), the Alamo and St. John, and

last, the Cumberland. Outside of this is the new concentrator of 100 tons daily capacity, which cost, for superstructure, machinery, etc., $30,000.

The reopening of the Comiquo at Kaslo has taken the rounder element from Three Forks and left the town much quieter. All winter long there has been so much hustle and rush here that the busy Three Forker spelled the name of his town "3 4x," but now the mercantile and hotel man has more time at his disposal.

IDAHO.

IDAHO MINES BONDED.—The Aspen and Mammoth gold mines, near the Yellow Jacket mines in Lemhi county, owned by D. M. Steen, Col. N. J. Sharp and A. J. Pierce, have been bonded to W. H. Savidge and J. M. Clark, representing New York capitalists, for $20,000, payable in quarterly installments of $5000 each after July 15th. The ore averages $15 per ton. The owners will put a force of men at work and it is expected in a few weeks the mines will be in full operation. Within two miles of the property two 10-stamp mills are located, where the quartz will be milled for the present. It is the intention to build a stamp mill with modern improvements.

A copper mine on Lost river, in Custer county, has been bonded to Loudon and New York capitalists, by Colonel N. J. Sharp, A. J. Pierce, R. M. Davidson and A. B. Reed, for $75,000. A forty-ton smelter will be erected. For the present the ore will be treated in the Houston smeltor near the property. The mine is said to be one of the best copper propositions in the State. It is estimated that there are at least 15,000 tons of ore in sight.

THE TIP-TOP PROPERTY.—*Idaho Nugget*: Col. Bryan is again back in Silver City and the Tip-Top mine is now being examined by experts in the interest of San Francisco parties with whom a deal is pending for the organization of a stock company, which will probably take charge of the property. In the bottom of the shaft the miners are now encountering ore quite different from that found nearer the surface. The ore is extremely rich in silver, similar in character to the silver-leads in the DeLamar mines. Specimens are being shown in Silver City which run up to several thousand ounces in value. These are not small specimens, but great masses. This rich ore having been encountered since the arrival of the experts, leaves but little doubt as to the nature of the report made on this famous property.

MONTANA.

RICH STRIKE REPORTED.—The *Tribune* says: Thomas Carmin, of Pony, Madison county, reports that he has struck a ten-inch vein of gold ore which runs $400 to the ton in the White Pine Lead.

Thomas Reynolds and other New York men have put up a large capital to control the Somerset Mining and Milling Company groups of properties on the Spanish Peaks in Huerfano county, and will work them extensively. The negotiations were made by Col. John T. Doweese, and the bond is for $300,000. Money for the work is up and the purchasers mean business. Work is to be commenced March 1st on a tunnel to be driven to great length on Wahatoyn ground and cut a number of veins which show good ore at the surface.

NEVADA.

SILVER STAR.—There are about 125 men at work at the Silver Star, and cabins are going up on the hillsides. The Hardscrabble has two shafts about 150 feet deep, and claims to have 4000 tons of $100 ore in sight. There will be a great deal of prospect work done there when the snow melts.

OREGON.

Josephine Co.

ALTHOUSE DISTRICT.—The Griffin ledge of quartz lies on the ridge between Althouse and Sucker creeks, three miles from Browntown, and is being put in position to grind its ore by a ten-stamp mill. A wagon-road on Democrat gulch will be built this year at a cost of $3000, and the distance covered will be about eighteen miles.

SOUTH DAKOTA.

THREE HUNDRED OUNCES.—Deadwood *Pioneer*: The cleanup at the Holy Terror, which was made Wednesday, netted 300 ounces of gold. This was only five days' run with five stamps and is a very successful one. The streak of ore from which this run was made still continues in the shaft and the amount of the find cannot be estimated as yet. Stoping will commence as soon as the 100-foot station is completed. Keystone people are feeling very good about the result of the cleanup, and a good camp is an assured fact.

UTAH.

INTERESTING MINING STATISTICS.—*Tribune*: The statistics now being collected and compiled under the direction of Colonel George B. Squires, chief of the Salt Lake County Bureau, will contain an interesting and important feature concerning the mining industry and the amount of money that has been invested without return. The opinion prevails among the Eastern goldites that the mountains of the West are solid silver, and that it costs comparatively nothing to produce the white metal. Colonel Squire's statistics will show the amounts that have been spent in developing mines in the West Mountain district, and the totals are astonishing. For instance, on one group $250,000 has been expended in development work, and on another $150,000, and this on properties that have not been producers.

THE MERCUR.—At the Mercur Gold Mining and Milling Company two shipments have been made. Between 125 and 150 tons of ore are now being treated by the mill, which takes everything as it comes from the mines, there being no waste dump. Assays of the tailings from the plant show that the values are being saved in the tanks and the general operation of the machinery is extremely satisfactory.

THE MAMMOTH.—Official returns received from the first carload of ore taken from the ore bodies recently uncovered on the 1000-foot and other lower levels of the Mammoth mine show that the strikes just made are fully as important as the famous one on the 800-foot level, out of which the company paid the greater portion of its dividends. They give an average of 30.6 ounces in gold, 3.66 ounces in silver and a slight percentage in copper and lead. The tests having been made by three local assayers Saturday on a lot of nineteen tons of ore, which was sold to the valley smelters during the afternoon. It is understood that regular shipments of this class of ore are to be made as long as the new deposits hold out. The value of this carload was $12,366.

THE GOLD MOUNTAIN.—The Gold Mountain mining district is to be equipped with its first cyanide plant soon, the recent tests of the ores from the properties of the Deseret Mining and Milling Company having shown conclusively that the chemicals will take care of the values, and the treatment by the cyanide process result in the saving of practically all of the gold in the ores. Average assays from the ore bodies recently opened up in the Silver King give returns of $35 in gold and a healthy showing of silver, for which metal the property and the others of the group were formerly worked.

NEW COTTONWOOD COMPANY.—*Tribune*: The Gold Point Mining & Milling Company with a capital stock of $1,500,000, divided into 150,000 shares of the par value of $10 each, has filed articles of incorporation. The incorporators consist of I. N. Parker, A. E. Short, J. L. May, H. T. Duke, W. B. Short, L. P. Palmor, C. A. Short and James Y. Smith, each of whom have subscribed for 15,000 shares, and all of whom constitute the board of directors. Harry T. Duke is president; I. N. Parker, vice-president; L. B. Palmer, secretary, and C. A. Short, treasurer. The property of the consists of the Gold Point, North Bend, Wonder, Standard and Gold Dust, situated between Big and Little Cottonwood canyons.

Twenty feet of work upon a tunnel is said to have disclosed three feet of gold-bearing quartz lying between the trachyte and granite, which shows from $15 to $50 gold. Secretary Palmer states that the ore shows very marked improvement as proceeded upon, and that the development of the property will be upon a most energetic scale.

WASHINGTON.

AT EVERETT.—A refinery and shot tower are contemplated at Everett. The concentrator at Monte Cristo will be started as soon as the hetter machinory can be put in. Two large contracts have been let for tunneling and development work in the Pride of the Mountains and Mystery mines, 208 men being employed. More machinery is being added to the concentrator because it was not big enough to take care of the ore coming from the mines and to keep a sufficient supply ahead for the Everett smelter. President McBride of the Monte Cristo Mining Company says that the concentrator will ship five times as much ore to the smelter in the future as it has in the past.

WYOMING.

A BIG ENTERPRISE.—J. B. Adams has completed the sale of placer gold mining claims below Boggs to New York and Rhode Island capitalists, and the money is being paid at present, says the Cheyenne *Sun*. This is a great enterprise, as over forty miles of ditch may be constructed, costing about $150,000. H. B. Gillespie, who has other property in the same locality, says he has secured the necessary funds to build the Slater and Elk Head ditches, which it is estimated will cost $250,000.

Chapman Hand Drill.

Realizing the extensive sale a first-class hand drill would have and the demand there was for a machine of this character that would give satisfaction, Mr. T. W. Chapman, formerly of Denver, went to work in a systematic manner to construct a drill which would be light enough for one man to handle and at the same time be compact and strong. By a series of experiments and a number of years experience with mining machinery, Mr. Chapman has at last secured what he considers the most perfect hand drill ever invented, comprising both simplicity and efficiency. The machine works upon a tripod with the "plunger movement," and the drill is withdrawn from the breast of the hole about two and one-quarter inches after each stroke and then turns partly around just before the next blow is given. The force of the blow can be regulated from sixty to one hundred and fifty pounds, and it is claimed one man with this machine can do more work than three men can do by hand. The Chapman Drill and Machine Co., of Chicago, Ill., are now putting this drill upon the market. *

THE Russian courts have reversed the assumption of the American tribunals that when a husband and wife are drowned in the same disaster the wife dies first. The Russian doctors have testified unanimously that the man would be the first to die, because the woman is more agile and keeps herself longer above water.

My Eastern Clients will Equip Prospects

For an interest or put cash and good Eastern property into good mines that are desirable. Give full details and fair prices and terms. CHARLES G. BARND, Atty., Box 2042, San Francisco, Cal.

Electrical Progress.

Electricity appears in "full dress" array this week in honor of the National Electric Light Convention at Cleveland, Ohio. The issue is a work of art and highly creditable to the profession.

MOTORMEN on the Mission street line commend the glass front cars built by Hammoud & Co. of this city. As compared to the open cars they are said to be a great protection to the health of motormen.

IT is said that the Market Street Railway Company contemplate an enlargement of their power-house to three times the present capacity at an early date. This company's lines will soon be entirely electric except on the high-grade routes.

THE Selby Smelting and Lead Company are making a special grade of lead plates for storage-battery purposes. The demand for these goods is said to be gradually increasing, and they are receiving a number of inquiries from different parts of the coast concerning the same.

THE question of underground conduits for electric railway trolley wires is again brought up in a lengthy article in a recent issue of the *Chronicle*. In this climate, and with more than half of the routes already conduited for cables, this should not prove a difficult task to successfully accomplish.

THE holders of the franchise for the new electric street railway in Berkeley intend to commence work at once. A system of transfers will be used in connection with the Grove street and Telegraph Avenue lines, which will practically provide transportation to all parts of Oakland.

THE *Electrical Review*, published at "13 Park Row, New York, was 13 years old last week, February 13th." Here's a trio of thirteens that's sure to continue good luck for the *Electrical Review*. Long life, continued success and prosperity to you. May your light continue to shine up to full standard.

THE unit used in measuring the strength of electric currents was first called "an ampere" by the French Electric Congress of 1881, the name being given to it in honor of Andre Marie Ampere, the French scientist, who elucidated the theory that the magnetism of the earth is the result of electric currents circulating around it from east to west.

ONE of the most interesting features of the N. E. L. A. Convention, held at Cleveland last week, was an informal address by Mr. Charles F. Bush, the well known pioneer in high-tension currents for light and power purposes. To those present who were familiar with the obstacles which Mr. Bush had to overcome before achieving his brilliant success this address must have proven of more than passing interest.

MESSRS. WHYTE AND DE ROME, the bronze and brass founders of this city, are doing a large amount of casting for the various electrical companies and electric railways. They are having a special demand at this time for their bronze castings. This firm manufactured the castings for the famous Lick historical statuary recently erected at the City Hall plaza. Their electrical sales agents are Messrs. Reager and Atwater of No. 214 Pine street.

THE Eureka Electric Company of this city are making a special feature of their new electric hand lamp. This lamp consists of a two-candle power lamp and a storage battery of about the size of an ordinary dark lantern, having a capacity of from four to five ampere hours. The lamp is lighted by the compression of a spring circuit-closer operated by the thumb, and the whole makes a neat and convenient apparatus. Primary batteries are provided for re-charging the cell when exhausted.

DURING the Electrical Congress held at the Chicago Expositiou a committee was appointed to consider the establishment of a system of units of electrical measuremeut, and the work, in the main, was left with the celebrated German physicist, Helmholtz. The death of this savant delayed the conclusion of the work. Not until the last week have the standards been agreed upon. Now the matter is in the hands of Prof. O. C. Marsh, of Yale, and he will forward his report to Washington.

R. DUNSMUIR & SONS, coal dealers of this city, are now operating their coal docks entirely by electricity, with the single exception of a hoist for screenings, which is required at all hours. The plant consists of two 90 K. W. generators; two locomotives of 15 H. P. each; and three coal hoists of 80 H. P. each. The combined capacity of the hoists is more than 1000 tons of coal per day. The electrical plant was provided by the General Electric Company and the steam power by H. P. Gregory & Co. of this city.

THE substitute for the ordinary forge, as proposed by George D. Burton of Boston, consists of a method of heating by plunging the metal into a vessel of water and passing a strong current of electricity through it, the apparatus comprising a wooden bucket containing a large sheet of lead, which forms the positive pole, and an iron bar laid across the bucket, forming the negative pole. The metal to be heated is held in the tongs, which are rested on this iron cross-piece and dipped into the liquid as desired, thus avoiding all flexible connections with the tongs. Two ordinary nails held in the tongs and dipped in the liquid are found to be heated to a welding heat in a few seconds, so as afterward to be welded on an anvil with a few blows of the hammer, or they may be welded by simply allowing them to fuse together. The solution which has been found best adapted to this purpose is a solution of ten parts carbonate of soda and one of borax dissolved in water until the specific gravity at 70° is 1.150.

EXCELLENT REPORTS of development and continuous working are received from the old Empire mine in Gold valley, Sierra county, California. The mine was bought last summer by the Gold Valley Mining Company, consisting of local and English capitalists. A thirty-stamp mill, hoisting works, etc., and a 150 h. p. electric plant were ordered in August. Snow began to fall early in November and very much interfered with the hauling of machinery and supplies. But by January 1st, notwithstanding the snow was ten feet deep, the electric plant was completed and started up operating the hoist and large air compressor. Ever since starting, the machinery has been in constant operation without a single stoppage of any kind. The electric machinery is said to be the finest ever erected on the coast, and was built specially for this work by the Electrical Engineering Company of 34 and 36 Main street, San Francisco. We are pleased to note the great amount of electric work the Engineering Company has done in mining apparatus on the coast and the unqualified success it has had in each instance. The company has in its employ first-class electrical and mining engineers, and, with its increased shop facilities, has a capacity for a large output on short notice.

THE *Practical Engineer*, in an editorial on economy of electricity in the scattered distribution of power, makes the statement that in using electricity as a means of conveying power, regard must always be had to the nature of the power it is to replace. We are all familiar with shops of one sort and another in which from one or two sets of boilers there are steam pipes carried long distances and individual machines driven each by its own small engine. Now it is not simply that small engines in themselves are so very wasteful; they rarely have the chance of showing what they can do with good dry steam and they are rarely indicated to show what amount of fuel they are really consuming. It is, however, to the use in them of steam cooled by exposure in long lengths of pipe that a large proportion of their inefficiency is due. They are employed because steam pipes can be run easier than shafting, and, once fixed, require no attention, whereas a shaft calls for continual attention in oiling and maintenance. As between a high-class steam engine and short, well protected pipes, and an electric motor taking current from a distant dynamo, it is held that no one would doubt the superiority of the engine. But when the superior engine drives a dynamo, and current is led off to motors at a distance, there is no question but that this is superior to the use of small steam engines.—Electricity.

Electric Portable Fire Engine.

There can be little question that an electric portable fire engine would be efficient and thoroughly practical were the question of current supply settled, and were it not that this part of the outfit, if properly installed and used for its special purpose only, would necessitate so great an outlay of money. But it is not absolutely necessary that a separate plant should be installed for the electric engine system. Where a city or district is well supplied with electric lighting, railway or power mains, distributed fairly well, and all of the same nature and voltage, these could be used for current supply by connecting them at intervals with suitable taps or switch boxes, which would be easily accessible, and to which the engine motor could be connected. It would not be necessary to have these switch boxes very close to the water plugs; they could be some distance away, and the cable, carried by the engine, would be attached to the nearest one. The electric supply mains and switch plugs or boxes would thus have to be only in the principal streets and avenues. The engine could be connected to any water plug without any regard to the location of the connection boxes, as enough flexible cable could always be carried on the engine to permit operating the engines at quite some distance from the distributing mains.—Cassier's Magazine.

Electrical Transmission of Water Power.

The utilization of water power electrically transmitted for mine operation is becoming more popular among mining men, as each installation demonstrates not only the feasibility of the system but also the economy which every such installation shows when compared with pre-existing systems which it displaces or which are in similar operation elsewhere.

A notable water power will shortly be utilized by the Ontario Silver Mining Co., of Park City, Utah. This company has recently completed a drain tunnel, said to be one of the greatest and most expensive undertakings ever carried out by a mining company, not even excepting the Sutro tunnel. It is three miles long and is now discharging from its mouth nearly 1000 cubic feet of water per minute. This water, under a head of 120 feet, will shortly be driving large low-frequency alternating current generators for power and light—the three-phase system of the General Electric Company being employed. The three-phase current generated from these machines will be transmitted round the mountain to the Ontario and Daly mines, five and a half miles from the generating station, and be used to drive the mills and to light the surrounding buildings. A portion of the current will also be taken to furnish light to the neighboring town of Park City. The voltage of the transmitted current is 2500 volts.
